(54) Title: METHODS AND APPARATUS FOR CONTROLLING ACCESS TO INFORMATION

(57) Abstract

A scalable access filter that is used together with others like it in a virtual private network to control access by users at clients in the network to information resources provided by servers in the network. Each access filter uses a local copy of an access control data base to determine whether an access request is made by a user. Changes made by administrators in the local copies are propagated to all of the other local copies. Each user belongs to one or more user groups and each information resource belongs to one or more information sets. Access is permitted or denied according to access policies which define access in terms of the user groups and information sets. The rights of administrators are similarly determined by administrative policies. Access is further permitted only if the trust levels of a mode of identification of the user and of the path in the network by which the access is made are sufficient for the sensitivity level of the information resource. If necessary, the access filter automatically encrypts the request with an encryption method whose trust level is sufficient. The first access filter in the path performs the access check and encrypts and authenticates the request; the other access filters in the path do not repeat the access check.

Background of the Invention

1. Field of the Invention

The invention relates generally to control of access to data and relates more specifically to control of access to data in a distributed environment.

2. Description of Related Art

The Internet has revolutionized data communications. It has done so by providing protocols and addressing schemes which make it possible for any computer system anywhere in the world to exchange information with any other computer system anywhere in the world, regardless of the computer system's physical hardware, the kind of physical network it is connected to, or the kinds of physical networks that are used to send the

information from the one computer system to the other computer system. All that is required for the two computer systems to exchange information is that each computer system have an Internet address and the software necessary for the protocols and that there be a route between the two machines by way of some combination of the many physical networks that may be used to carry messages constructed according to the protocols.

The very ease with which computer systems may exchange information via the Internet has, however, caused problems. On the one hand, it has made accessing information easier and cheaper than it ever was before; on the other hand, it has made it much harder to protect information. The Internet has made it harder to protect information in two ways:

- It is harder to restrict access. If information may be accessed at all via the Internet, it is potentially accessible to anyone with access to the Internet. Once there is Internet access to information, blocking skilled intruders becomes a difficult technical problem.
- It is harder to maintain security en route through the Internet. The Internet is implemented as a packet switching network. It is impossible to predict what route a message will take through the network. It is further impossible to ensure the security of all of the switches, or to ensure that the portions of the message, including those which specify its source or destination, have not been read or altered en route.

FIG. 1 shows techniques presently used to increase security in networks that are accessible via the Internet. FIG. 1 shows network 101, which is made up of two separate internal networks 103(A) and 103(B) that are connected by Internet 111. Networks 103(A) and 103(B) are not generally accessible, but are part of the Internet in the sense that computer systems in these networks have Internet addresses and employ Internet protocols to exchange information. Two such computer systems appear in FIG. 1 as requestor 105 in network 103(A) and server 113 in network 103(b). Requestor 105 is requesting access to data which can be provided by server 113. Attached to server 113

is a mass storage device 115 that contains data 117 which is being requested by requestor 105. Of course, for other data, server 113 may be the requestor and requestor 105 the server. Moreover, *access* is to be understood in the present context as any operation which can read or change data stored on server 113 or which can change the state of server 113. In making the request, requestor 105 is using one of the standard TCP/IP protocols. As used here, a *protocol* is a description of a set of messages that can be used to exchange information between computer systems.

The actual messages that are sent between computer systems that are communicating according to a protocol are collectively termed a *session*. During the session, Requestor 105 sends messages according to the protocol to server 113's Internet address and server 113 sends messages according to the protocol to requestor 105's Internet address. Both the request and response will travel between internal network 103(A) and 103(B) by Internet 111. If server 113 permits requestor 105 to access the data, some of the messages flowing from server 113 to requestor 105 in the session will include the requested data 117. The software components of server 113 which respond to the messages as required by the protocol are termed a *service*.

If the owner of internal networks 103(A and B) wants to be sure that only users of computer systems connected directly to networks 103(A and B) can access data 117 and that the contents of the request and response are not known outside those networks, the owner must solve two problems: making sure that server 113 does not respond to requests from computer systems other than those connected to the internal networks and making sure that people with access to Internet 111 cannot access or modify the request and response while they are in transit through Internet 111. Two techniques which make it possible to achieve these goals are *firewalls* and *tunneling* using encryption.

Conceptually, a firewall is a barrier between an internal network and the rest of Internet 111. Firewalls appear at 109(A) and (B). Firewall 109(A) protects internal network 103(A) and firewall 109(B) protects internal network 103(B). Firewalls are implemented by means of a gateway running in a computer system that is installed at the point where an internal network is connected to the Internet. Included in the gateway is an *access*

filter: a set of software and hardware components in the computer system which checks all requests from outside the internal network for information stored inside the internal network and only sends a request on into the internal network if it is from a sources that has the right to access the information. Otherwise, it discards the request. Two such access filters, access filter 107(A), and access filter 107(B), appear in FIG. 1.

A source has the right to access the requested information if two questions can be answered affirmatively:

- Is the source in fact who or what it claims to be?
- Does the source have the right to access the data?

The process of finding the answer to the first question is termed *authentication*. A user authenticates himself or herself to the firewall by providing information to the firewall that identifies the user. Among such information is the following:

- information provided by an *authentication token* (sometimes called a smartcard) in the possession of the user;
- the operating system identification for the user's machine; and
- the IP address and the Internet domain name of the user's machine.

The information that the firewall uses for authentication can either be *in band*, that is, it is part of the protocol, or it can be *out of band*, that is, it is provided by a separate protocol.

As is clear from the above list of identification information, the degree to which a firewall can trust identification information to authenticate a user depends on the kind of identification information. For example, the IP address in a packet can be changed by anyone who can intercept the packet; consequently, the firewall can put little trust in it and authentication by means of the IP address is said to have a very low *trust level*. On the other hand, when the identification information comes from a token, the firewall can give the identification a much higher trust level, since the token would fail to identify the user only if it had come into someone else's possession. For a discussion on authentication generally, see S. Bellovin and W. Cheswick, *Firewalls and Internet Security*, Addison Wesley, Reading, MA, 1994.

In modern access filters, access is checked at two levels, the *Internet packet*, or *IP* level, and the *application* level. Beginning with the IP level, the messages used in Internet protocols are carried in packets called datagrams. Each such packet has a header which contains information indicating the source and destination of the packet. The source and destination are each expressed in terms of IP address and port number. A *port number* is a number from 1 to 65535 used to individuate multiple streams of traffic within a computer. Services for well-known Internet protocols (such as HTTP or FTP) are assigned well known port numbers that they 'listen' to. The access filter has a set of rules which indicate which destinations may receive IP packets from which sources, and if the source and destination specified in the header do not conform to these rules, the packet is discarded. For example, the rules may allow or disallow all access from one computer to another, or limit access to a particular service (specified by the port number) based on the source of the IP packet. There is, however, no information in the header of the IP packet about the individual piece of information being accessed and the only information about the user is the source information. Access checking that involves either authentication of the user beyond what is possible using the source information or determining whether the user has access to an individual piece of information thus cannot by done at the IP level, but must instead be done at the protocol level.

Access checking at the application level is usually done in the firewall by *proxies*. A proxy is a software component of the access filter. The proxy is so called because it serves as the protocol's stand-in in the access filter for the purposes of carrying out user authentication and/or access checking on the piece of information that the user has requested. For example, a frequently-used TCP/IP protocol is the hyper-text transfer protocol, or HTTP, which is used to transfer World-Wide Web pages from one computer to another such computer system. If access control for individual pages is needed, the contents of the protocol must be inspected to determine which particular Web page is requested. For a detailed discussion of firewalls, see the Bellovin and Cheswick reference *supra*.

While properly-done access filtering can prevent unauthorized access via Internet 111 to

data stored in an internal network, it cannot prevent unauthorized access to data that is in transit through Internet 111. That is prevented by means of tunneling using encryption. This kind of tunneling works as follows: when access filter 107(A) receives an IP packet from a computer system in internal network 103(A) which has a destination address in internal network 103(B), it encrypts the IP packet, including its header, and adds a new header which specifies the IP address of access filter 107(A) as the source address for the packet and the IP address of access filter 107(B) as the destination address. The new header may also contain authentication information which identifies access filter 107(A) as the source of the encrypted packet and information from which access filter 107(B) can determine whether the encrypted packet has been tampered with.

Because the original IP packet has been encrypted, neither the header nor the contents of the original IP packet can be read while it is passing through Internet 111, nor can the header or data of the original IP packet be modified without detection. When access filter 107(B) receives the IP packet, it uses any identification information to determine whether the packet is really from access filter 107(A). If it is, it removes the header added by access filter 107(A) to the packet, determines whether the packet was tampered with and if it was not, decrypts the packet and performs IP-level access checking on the original header. If the header passes, access filter 107(B) forwards the packet to the IP address in the internal network specified in the original header or to a proxy for protocol level access control. The original IP packet is said to *tunnel* through Internet 111. In FIG. 1, one such tunnel 112 is shown between access filter 107(A) and 107(B). An additional advantage of tunneling is that it hides the structure of the internal networks from those who have access to them only from Internet 111, since the only unencrypted IP addresses are those of the access filters.

The owner of internal networks 103(A) and 103(B) can also use tunneling together with Internet 111 to make the two internal networks 103(A and B) into a single *virtual private network (VPN)* 119. By means of tunnel 112, computer systems in network 103(A) and 103(B) can communicate with each other securely and refer to other computers as if network 103(A) and 103(B) were connected by a private physical link instead of by

Internet 111. Indeed, virtual private network 119 may be extended to include any user who has access to Internet 111 and can do the following:

- encrypt Internet packets addressed to a computer system in an internal network 103 in a fashion which permits an access filter 107 to decrypt them;
- add a header to the encrypted packet which is addressed to filter 107; and
- authenticate him or herself to access filter 107.

For example, an employee who has a portable computer that is connected to Internet 111 and has the necessary encryption and authentication capabilities can use the virtual private network to securely retrieve data from a computer system in one of the internal networks.

Once internal networks begin using Internet addressing and Internet protocols and are connected into virtual private networks, the browsers that have been developed for the Internet can be used as well in the internal networks 103, and from the point of view of the user, there is no difference between accessing data in Internet 111 and accessing it in internal network 103. Internal network 103 has thus become an *intranet*, that is, an internal network that has the same user interface as Internet 111. Of course, once all of the internal networks belonging to an entity have been combined into a single virtual private intranet, the access control issues characteristic of the Internet arise again--except this time with regard to *internal* access to data. While firewalls at the points where the internal networks are connected to Internet 111 are perfectly sufficient to keep outsiders from accessing data in the internal networks, they cannot keep *insiders* from accessing that data. For example, it may be just as important to a company to protect its personnel data from its employees as to protect it from outsiders. At the same time, the company may want to make its World Wide Web site on a computer system in one of the internal networks 103 easily accessible to anyone who has access to Internet 111.

One solution to the security problems posed by virtual private intranets is to use firewalls to subdivide the internal networks, as well as to protect the internal networks from unauthorized access via the Internet. Present-day access filters 107 are designed for protecting the perimeter of an internal network from unauthorized access, and there is typically only one access filter 107 per Internet connection. If access filters are to be used

within the internal networks, there will be many more of them, and virtual private networks that use multiple present-day access filters 107 are not easily *scalable*, that is, in virtual private networks with small numbers of access filters, the access filters are not a serious burden; in networks with large numbers of access filters, they are. Among the problems posed by present-day access filters when they are present in large numbers in a virtual private network are the following:

- Present-day access filters are designed to be centrally-administered by a small number of data security experts. As the number of access filters increases, central administration becomes too slow, too expensive, and too error-prone.
- Present-day access filters are designed on the assumption that there are only a small number of access filters between the source and destination for data. Where there are many, the increase in access time and the reduction in access speed caused by the filters becomes important.
- Present-day access filters are designed on the assumption that the Internet side of the filter is completely insecure and the internal network side of the filter is completely secure. In fact, both kinds of networks offer varying degrees of security. Because security adds overhead, the access filter should neither require nor provide more than is necessary.
- Present-day access filters, where they use encryption, require that each access filter know encryption keys for each other access filter. Large numbers of access filters require substantial duplicated effort in key maintenance.
- Present-day access filters do not provide any mechanism for giving the user a view of the information resources that corresponds to the user's access rights.

What is needed if intranets and virtual private networks are to achieve their full promise is access filters that do not present the above problems for scalability.

Summary of the Invention

One aspect of providing access filters that do not cause scalability problems is decentralized administration of access filters. The decentralized administration is done

using two classes of policy:

- access policy, which determine how users may access information. The users belong to sets of users called *user groups* and the information belongs to sets of resources called *information sets* and access policy is defined in terms of access by user groups to information sets; and
- administrative policy, which determines how administrators may administer and delegate access policies and the subjects and objects of access policies. Administrative policy is defined in terms of sets of administrative users and objects.

A member of an administrative user set which administers an object may make administrative policy for the object; this permits an administrative user set to delegate its right to administer the object to another administrative user group. The access policy is administered by means of policy maker policy, which is how administrative user groups may make access policy. The policy maker policy is defined in terms of administrative user groups and sets of resources.

When the access filter is set up, a built-in administrative policy gives a built-in administrative user group called the *security officer* the right to make administrative policy for all objects in the system. Members of the security officer user group delegate rights to make administrative policy to other administrative user groups as required for the VPN in which the access filter is installed. Generally, the policy maker policy is set up to give only a small number of high-level security experts the right to make access policy. The remaining administrative policy is delegated to user groups who have the requisite knowledge of the entities being administered. For example, if a user group corresponds to a department in a business, administration of the departmental user group may be delegated to the departmental secretary.

The entities in the virtual private network to which the access filter belongs are hierarchically organized. In general, entities at a lower level of the hierarchy *inherit* policies which apply at higher levels. Thus, the access policies which apply to a user group also apply to its subsets and an administrator who has administrative access to the

user group also has administrative access to its subsets.

Delegation is done by changing the administrative policy. To delegate administration of the user group to the departmental secretary, the administrator for the administrative user group that administers the departmental user group adds the departmental secretary to the administrative user group. If that administrative user group administers other user groups as well and it is desired to give the departmental secretary administrative authority *only* over the departmental user group, the administrator for the administrative user group makes a new administrative user group that contains only the departmental secretary and the administrator who defines administrative policy for the departmental user group adds an administrative policy which permits the new administrative user group containing the departmental secretary to administer the departmental user group. The departmental secretary can now add members to and delete members from the departmental user group. Because of inheritance, anyone who belongs to an administrative user group which can administer a user group which is above the departmental user group in the hierarchy can also administer the departmental user group.

Among the objects to which administrative policies apply are user groups, information sets, and available resources, that is, the services, servers, access filters, and network structure making up the virtual private network. The administrator of an object also controls attributes of the object such as the sensitivity level of resources and the trust level of modes of user identification, network links, and encryption methods.

The access policy and the administrative policy are defined in access control information. Each access filter has a local copy of the access control information. An administrative user may edit the local copy and changes are propagated to the other access filters in the virtual private network. One of the access filters has a master copy, and changes are first propagated to the master copy and the changed master copy is then propagated to all of the other access filters.

Administration of the access policy and of the entities is done by means of graphical user

interfaces. The graphical user interface for administering an access policy has a three-part display; in one part, the user groups are displayed; in a second part, the information sets to which the user groups are to be given data access are displayed; in a third part, the policies are displayed. In creating a new policy, a user group is selected in the first part, an information set is selected in the second part, and a policy is defined. The new policy then appears in the third part. An evaluator in the graphical user interface permits the user to see how current policies affect access by user groups to information sets. The graphical user interface for administering an object has a list of entities that the user using the interface can administer and a set of administrative operations.

Another aspect of providing access filters that do not cause scalability problems is providing the user with a view of the information resources available in the network which corresponds to the user's access privileges. This is done with a user interface that includes an access control information reader that responds to an identification of a user by reading the access control information in an access filter to determine at least those resources to which the user potentially has access and providing a list of those resources to an interface display generator which responds to the list by generating a display which visually indicates those resources to which the user potentially has access. The user may filter and sort the information resources shown on the display in various fashions and can also perform searches on them. The filtration and search operations are limited to the resources on the list.

Another aspect of the user interface include indications in the list and in the display of how the user may access the resources. When the method is by means of a hyperlink, the list contains the hyperlink and selection of the resource by the user activates the hyperlink. The list may also show resources to which the user presently does not have access, but for which the user may request access. With such resources, the list includes the e-mail address of an administrator for the agent and when the user selects the resource, the user interface provides an interface for sending an e-mail message to the administrator.

The user interface may be implemented by including the access control information reader

in the access control system and the display generator in a client from which the user requests access. In networks with access filters, the access control information reader may be implemented in an access filter. Where there are multiple copies of the access control information, the access control information reader in the access filter local to the client may provide the list to the client. It is particularly advantageous to implement the display generator as a downloadable program. When a user wishes to use the interface, the downloadable program is downloaded to the user's client. The access control information reader is implemented as a proxy on the local access filter. The proxy intercepts the downloadable program's request for the list and uses the local copy of the access control information to make the list. It should be noted here that while the user interface is particularly advantageous in a network, it may be employed in any situation where access by users to information is mediated by an access control system.

A further aspect of providing access filters that do not cause scalability problems is that of providing only as much authentication and encryption security as is required for a given user, a given path through the network, and a given resource. That is done using a set of techniques which are collectively termed herein Secure Encrypted Network Delivery, or SEND. In SEND, each information resource is assigned a sensitivity level. For example, the lowest sensitivity level may be *public*, meaning that anyone in the Internet can access the resource, and the highest may be *top secret*. Each user is further identified according to one or more modes of identification such as an IP address, a token, or a certificate. Each of these modes of identification is assigned a trust level from the same set of names as the sensitivity levels. When a user makes a request to access an information item, the access filter will grant the access only if the trust level for the mode of identification that the user employs in the request is no lower than the sensitivity level of the resource. If the trust level of the mode of identification employed to identify the user is too low, the access filter may request identification by a mode of identification having a higher trust level.

The path that the request takes through the network from the user to the location of the information resource also has a trust level. The trust level of the path is known to the

access filter, and the access filter will permit the user to access the information resource only if the trust level of the path is no lower than the sensitivity level of the resource. Where the path has several segments, the trust level of the path is the lowest trust level of any of its segments.

Methods of encryption also have trust levels. Where the trust level of the path between the user and the access filter is insufficient for the sensitivity level of the resource, the access filter will forward the access request only if the user has encrypted the request with an encryption method whose trust level is sufficient for the sensitivity level. Where the trust level of the path between the access filter and the resource is insufficient, the access filter will automatically encrypt the access request using the minimum encryption method that has a sufficient trust level.

In a preferred embodiment, an access request for a resource will not be forwarded by the access filter unless the trust level of the mode of identification employed by the user and either the trust level of the path taken by the request through the network or the trust level of the encryption method used to encrypt the request are sufficient for the sensitivity level of the resource. SEND thus ensures that the effort expended in making the access request secure is directly proportional to the degree of security required by the resource and the degree of insecurity of the mode of identification of the user, of the path through the network, or of the encryption method. It should be pointed out at this point that the techniques embodied in SEND are not restricted to access filters, but can be employed in any situation where a user accesses an information resource.

A still further aspect of providing access filters which do not cause scalability problems is providing an access filter which has an access check confirmer that determines whether another access filter has already made a determination whether the user may request the access. The access check confirmer causes the access filter to make the determination only if the determination has not been made by another access filter. Having made the determination, the access filter adds authentication information to the access request indicating that the access filter has made the determination. In one embodiment, the

authentication information is inherent in the use of encryption destined for another access filter in the VPN, where all of the access filters in the VPN authenticate each other via certificates signed by mutually trusted certificate authorities. Encryption may be by one of several methods. The access filter that first handles a request for data selects a method which is sufficient for a sensitivity level of the resource being accessed. After encrypting the access request, the other access filter adds authentication information as described above.

In another aspect of the invention, each of the access filters has a local copy of access control information and an access checker that uses the local copy to determine whether the user may access the resource. Each access filter further includes an editor for making changes in the local copy and a change propagator for propagating the changes to others of the plurality of access filters. Included in the local copy of the access control information is information indicating whether a given user may make a change in a predetermined part of the local copy. The access control information also permits a user who has the right to make a change in the predetermined part of the local copy to delegate that right to another user.

Other objects and advantages of the invention will be apparent to those skilled in the arts to which the invention pertains upon perusing the following *Detailed Description* and Drawing, wherein:

Brief Description of the Drawing

FIG. 1 is an overview of techniques used to control access of information via the Internet;

FIG. 2 is an overview of a VPN that uses access filters incorporating the techniques disclosed herein;

FIG. 3 is an overview of an access control database that is used in the access filters;

FIG. 4 shows access checking and tunneling in a VPN that uses access filters incorporating the techniques disclosed herein;

FIG. 5 shows access by a "roamer" to information in the VPN;

FIG. 6 is a table used in defining the relationship between sensitivity and trust levels and

authentication and encryption techniques;

FIG. 7 is an example of the application of SEND;

FIG. 8 is a flow chart of the policy creation process;

FIG. 9 shows a display used to define user groups;

FIG. 10 shows a display used to define information sets;

FIG. 11 shows a display used to define access policies;

FIG. 12 shows a display used to define an access filter 203;

FIG. 13 is a schema of the part of access control database 301 that defines user groups;

FIG. 14 is a schema of the part of access control database 301 that defines information sets;

FIG. 15 is a schema of the part of access control database 301 that defines sites in the VPN

and the servers, services, and resources at each site;

FIG. 16 is a schema of the part of access control database 301 that defines policies;

FIG. 17 is a schema of the part of access control database 301 that defines servers;

FIG. 18 shows the display used in the IntraMap interface;

FIG. 19 shows how changes are made to access control database 301;

FIG. 20 is a detailed block diagram of the architecture of an access filter 203;

FIG. 21 is a diagram of the structure of an MMF file 2303;

FIG. 22 is a diagram of a message sent using SKIP;

FIGs. 23A, B, and C are a table of the MMF files employed in a preferred embodiment;

FIG. 24 is a diagram of an implementation of the IntraMap interface; and

FIG. 25 is a diagram illustrating delegation in VPN 201.

The reference numbers in the drawings have at least three digits. The two rightmost digits are reference numbers within a figure; the digits to the left of those digits are the number of the figure in which the item identified by the reference number first appears. For example, an item with reference number 203 first appears in FIG. 2.

Detailed Description

The following *Detailed Description* will first provide an overview of access filters that are

easily scalable, of how they are used to control access in intranets, and of how they can be used to construct virtual private networks. Thereupon, the *Detailed Description* will provide details of the access control database used in the filters, of the manner in which it is changed and those changes are distributed among the filters, and of the manner in which an individual filter controls access.

A Network with Access Filters that do not Interfere with Scalability: FIG. 2

FIG. 2 shows a virtual private network (VPN) 201 in which access to data is controlled by access filters that are designed to avoid the problems posed by multiple access filters.. VPN 201 is made up of four internal networks 103 which are connected to each other by Internet 121. Also connected to VPN 201 via Internet 121 is a roamer 217, that is, a computer system which is being used by a person who may access data in intranet 201, but is connected to the internal networks only by Internet 121. Each internal network 103 has a number of computer systems or terminals 209 belonging to users and a number of servers 211 which contain data that may be accessed by users at systems or terminals 209 or by a user at roamer 217. However, no computer system or terminal 209 or roamer 217 is connected directly to a server 211; instead, each is connected via an access filter 203, so that all references made by a user at a user system to a data item on a server go through at least one access filter 203. Thus, user system 209(i) is connected to network 213(i), which is connected to access filter 203(a), while server 211(i) is connected to network 215(i), which is also connected to access filter 203(a), and any attempt by a user at user system 209(i) to access data on server 211(i) goes through access filter 203(a), where it is rejected if the user does not have the right to access the data.

If VPN 201 is of any size at all, there will be a substantial number of access filters 203, and consequently, scaling problems will immediately arise. Access filters 203 avoid these problems because they are designed according to the following principles:

- **Distributed access control database.** Each access filter 203 has its own copy of the access control database used to control access to data in VPN 201. Changes made in one copy of the database are propagated to all other copies.
- **Distributed administration.** Any number of administrators may be delegated

responsibility for subsets of the system. All administrators may perform their tasks simultaneously.

- **Distributed access control**. Access control functions are performed at the near-end access filter 203. That is, the first access filter 203 in the path between a client and the server determines if the access is allowed and subsequent access filters in the path do not repeat the access checks made by the first access filter.
- **End-to-end encryption**. Encryption occurs between the near-end access filter and the furthest encryption endpoint possible. This endpoint is either the information server itself or the far-end access filter 203 —the one last in the route from client to server. Dynamic tunnels are created based on current network routing conditions
- **Adaptive encryption and authentication**. Variable levels of encryption and authentication requirements are applied to traffic passed through the VPN, based on the sensitivity of the information being transmitted.

All of these aspects of the design will be discussed in more detail below.

It should be pointed out at this point that access filter 203 may be implemented in any fashion which ensures that all references to data in VPN 201 which are made by users who may not be authorized to access that data go through an access filter 203. In a preferred embodiment, access filter 203 is implemented on a server and runs under the Windows NT® operating system manufactured by Microsoft Corporation. In other embodiments, access filter 203 may be implemented as a component of an operating system and/or may be implemented in a router in VPN 201.

Distributed Policy Database: FIG. 3

Each access filter 203 has a copy of an access control database 301 that holds all data relevant to access control in VPN 201. One access filter, shown as access filter 203(a) in FIG. 2, has a master copy 205 of access control database 301. Because of this, access filter 203(a) is termed the *Master Policy Manager*. The master copy 205 is the one that is used to initialize new access filters 203 or replace a damaged access control database 301. The backup for the master policy manager computer is access filter 203(b). Backup

207 is a mirror image of master copy 205. Report manager 209, finally, includes software for generating reports from the information in access control database 301 and from logs obtained from all other access filters 203. Any copy of access control database 301 may be altered by any user who has the access required to do so; as will be described in more detail later, any such alteration is propagated first to master policy manager 205 and then to all of the other access filters 203 in virtual private network 201.

FIG. 3 is a conceptual overview of access control database 301. The primary function of the database is to respond to an access request 309 from access filter 203 which identifies a user and an information resource with an indication 311 of whether the request will be granted or denied. The request will be granted if *both* of the following are true:

- The user belongs to a *user group* which data base 301 indicates may access an *information set* to which the information resource belongs; and
- the request has a *trust level* which is at least as high as a *sensitivity level* belonging to the information resource.

Each user belongs to one or more of the user groups and each information resource belongs to one or more information sets; if none of the user groups that the user belongs to is denied access to an information set that the resource belongs to and any of the user groups that the user belongs to is allowed access to any of the information sets that the information resource belongs to, the user may access the information resource, *provided that* the request has the requisite trust level.

The sensitivity level of a resource is simply a value that indicates the trust level required to access the resource. In general, the greater the need to protect the information resource, the higher its sensitivity level. The trust level of a request has a number of components:

- the trust level of the identification technique used to identify the user; for example, identification of a user by a token has a higher trust level than identification of the user by IP address.
- the trust level of the path taken by the access request through the network; for example, a path that includes the Internet has a lower trust level than one that

includes only internal networks.

- if the access request is encrypted, the trust level of the encryption technique used; the stronger the encryption technique, the higher the trust level.

The trust level of the identification technique and the trust level of the path are each considered separately. The trust level of the path may, however, be affected by the trust level of the encryption technique used to encrypt the access request. If the request is encrypted with an encryption technique whose trust level is higher that the trust level of a portion of the path, the trust level of the portion is increased to the trust level of the encryption technique. Thus, if the trust level of a portion of a path is less than required for the sensitivity level of the resource, the problem can be solved by encrypting the access request with an encryption technique that has the necessary trust level.

The information contained in database 301 may be divided into five broad categories:

- user identification information 313, which identifies the user;
- user groups 315, which defines the groups the users belong to;
- information resources 320, which defines the individual information items subject to protection and specifies where to find them;
- information sets 321, which defines groups of information resources;
- trust information 323, which specifies the sensitivity levels of information resources and the trust levels of user identifications and network paths; and
- policy information 303, which defines access rights in terms of user groups and objects in VPN 201.

Policy information is further divided into access policy 307, administrative policy 305, and policy maker policy 306.

- access policy 307 defines rights of access by user groups to information sets;
- administrative policy 305 defines rights of user groups to define/delete/ modify objects in VPN 201. Among the objects are access policies, information sets, user groups, locations in VPN 201, servers, and services; and
- policy maker policy 306 defines rights of user groups to make access policy for information sets.

The user groups specified in the administrative policy and policy maker policy portions of database 301 are user groups of *administrators*. In VPN 201, administrative authority is delegated by defining groups of administrators and the objects over which they have control in database 301. Of course, a given user may be a member of both ordinary user groups 317 and administrative user groups 319.

Identification of Users

User groups identify their members with user identification information 313. The identification information identifies its users by means of a set of extensible identification techniques. Presently, these identification techniques include X.509 certificates, Windows NT Domain identification, authentication tokens, and IP address/domain name. The kind of identification technique used to identify a user determines the trust level of the identification.

Where strong identification of a user or other entity that an access filter 203 communicates with is required, VPN 201 employs the Simple Key Management for Internet Protocols (SKIP) software protocol, developed by Sun Microsystems, Inc. The protocol manages public key exchange, authentication of keys, and encryption of sessions. It does session encryption by means of a transport key generated from the public and private keys of the parties who are exchanging data. Public keys are included in X.509 certificates that are exchanged between SKIP parties using a separate protocol known as the Certificate Discovery Protocol (CDP). A message that is encrypted using SKIP includes in addition to the encrypted message an encrypted transport key for the message and identifiers for the certificates for the source and destination of the data. The recipient of the message uses the identifiers for the certificate of the source of the message to locate the public key for the source, and uses its keys and the source's public key to decrypt the transport key and uses the transport key to decrypt the message. A SKIP message is self-authenticating in the sense that it contains an authentication header which includes a cryptographic digest of the packet contents and modification of any kind will render the digest incorrect. For details on SKIP, see Ashar Aziz and Martin Patterson, *Simple Key-Management for Internet Protocols (SKIP)*, which could be found on 2/28/98 at `http://www.skip.org/inet-95.html`. For details on X.509 certification, see

the description that could be found on 9/2/97 at http://www.rnbo.com/PROD/rmadillo/p/pdoc2.htm.

In VPN 201, SKIP is also used by access filters 203 to identify themselves to other access filters 203 in the VPN and to encrypt TCP/IP sessions where that is required. Access filters 203 can also use the certificates for the SKIP keys to identify users when they are performing access checks. Such an identification is particularly trustworthy and has a correspondingly high trust level. One use for such identification by mean of certificate is for trustworthy identification of a "roamer" 217. The X.509 certificates can be used for user identification because they relate the key information to information about the user.

Access filter 203 uses the following fields of information from the certificates:

- Expiration Date. The date after which the certificate is invalid.
- Public Key. The public half of a public-private key pair, as used in the SKIP-based cryptography that Conclave uses.
- Certificate Authority Signature. The distinguished name associated with the authority that issued the certificate.
- Serial Number for the certificate
- Subject name, the name of the entity the certificate was issued to.

The subject name includes the following subfields (the value in parentheses is the common abbreviation for the field):

- Common Name (CN). The given name of the subject, for example, John Q. Public.
- Country (C). The country in which the subject resides. Country codes are 2-letter codes specified in the X.509 specification.
- Locality (L). The location at which the subject resides. This is usually the city in which the subject resides, but can be used for any location-related value.
- Organization (O). The organization to which the subject belongs. This is usually the organization's name.
- Organizational Unit (OU). The organizational unit for the subject. This is usually the department for the subject, for example, "sales". The X.509 certificate allows

up to four of these fields to exist.

A Certificate Authority used with access filters 203 issues certificates with all of these fields. Further, the four OU fields can be used to define additional categories. The information used to describe a user in a certificate is available to the administrators of data base 301 for use when defining user groups. If the information in the certificates properly reflects the organizational structure of the enterprise, a certificate will not only identify the user, but show where the user fits in the enterprise's organization and to the extent that the user groups in data base 301 reflect the organizational structure, the user groups that the user belongs to.

As will be explained in more detail later, one way in which members of user groups may be defined is by *certificate matching criteria* which define the values of the fields which a certificate that belongs to a member of a given user group must have. The certificate matching criteria can be based on as few or as many of the above fields as desired. For example, the certificate matching criteria for the `Engineering` user group might be the organization field and an organization unit field specifying the engineering department. Other information that identifies a user may be used to define members of user groups as well.

Information Sets

Information sets hold collections of individual information resources. A resource may be as small as an individual WWW page or newsgroup, but most often it will consist of a Web directory tree and its contents, FTP accounts, or major Usenet news categories. Two information sets, 219(j) and (k), are shown in one of the servers of FIG. 2. While it is completely up to the administrators of access control database 301 to determine what information is included in an information set, the information in a given set will generally be information that is related both topically and by intended audience. Example information sets for a corporation might be `HR policies`, `HR Personnel Records`, and `Public Information`.

Access Policy 307

Conceptually, access policy 307 consists of simple statements of the form:

```
Engineers       allowed access to   engineering data
Internet        allowed access to   public web site
```

The first column specifies user groups; the last column specifies information sets. The middle column is the access policy—allow or deny.

Database 301 permits hierarchical definition of both user groups and information sets. For example, the `Engineers` user group may be defined as including a `Hardware Engineers` user group, a `Software Engineers` user group, and a `Sales Engineers` user group. Similarly, the `engineering data` information set may be defined as including a `hardware engineering data` information set, a `software engineering data` information set, and a `sales engineering data` information set. Access rights are inherited within hierarchies of user groups. Thus, a user who belongs to the `Hardware Engineers` user group also automatically belongs to the `Engineers` user group for access checking purposes. Access rights are similarly inherited within hierarchies of information sets. An information resource that belongs to the `hardware engineering` information set also automatically belongs to the `engineering data` information set for access checking purposes. Thus, if there is an access policy that gives `Engineers` access to `engineering data`, any user who is a member of one of the three user groups making up `Engineers` may access any information resource that belongs to any of the three information sets making up `engineering data`. The use of inheritance in the definitions of user groups and information sets greatly reduces the number of access policies 307 that are required in access control database 301. For instance, in the above example, a single access policy gives all engineers access to all engineering data. Inheritance also makes it possible to define virtually all access policies in terms of allowing access. Continuing with the above example, if there is a user group `Salespeople` that does not belong to `Engineers` and there is an access policy that gives that user group access to `sales engineering data`, a user who is a member of `Salespeople` will be able to access `sales engineering data`, but not `software engineering data` or `hardware`

engineering data.

A user may of course belong to more than one user group and an information resource may belong to more than one information set. There may also be different access policies for the various user groups the user belongs to and the various information sets the information resource belongs to. When faced with multiple access policies that apply to the user and to the information resource that the user is seeking to access, access filter 203 applies the policies in a restrictive, rather than permissive way:

- If multiple policies allow or deny a user group's access to an information set, policies that deny access prevail.
- If a particular user is a member of multiple user groups, and multiple policies allow or deny access to the information set, policies that deny access prevail.

What user groups a user belongs to may vary according to the mode of identification used to identify the user. Thus, if no access policies apply for the user groups that the user belongs to according to the modes of identification that the user has thus far provided to access filter 203, access filter 203 may try to obtain additional identification information and determine whether the additional identification information places the user in a user group for which there is a policy regarding the resource. Access filter 203 may obtain the additional identification information if:

- The user has installed the User Identification Client (software that runs on the user's machine and provides identification information about the user to access filter 203).
- The UIC is currently running on the user's machine.
- The user has enabled his UIC to pop-up for further authentication. (The user has a check box that enables this feature.)

If all of these requirements are true, then access filter 203 will force the user's UIC to pop-up and ask for further identification information. Any identification information that the user supplies is saved. After each new piece of user identification information, access filter 203 performs the same evaluation process, popping up the UIC window until identification information is obtained that places the user in a user group for which there is an access

policy that permits or denies access or until the user gives up on his or her request.

Administrative policies 305

The administrative policies 305 implement administration of objects in VPN 201's access control system. Included in the objects are user groups, information sets, access policies, and what are termed herein *available resources*, that is, the services, servers, access filters, and network hardware making up VPN 201. An object is administered by one or more *administrative user groups*. A member of an administrative user group that administers a given object may modify the object and its relationship to other objects and may make administrative policy for the object. As will be explained in more detail later, the fact that a member of an administrative user group that administers an object may make administrative policy for the object makes it possible for the member to *delegate* administration of the object. For example, a member of an administrative user group that administers a `Hardware Engineers` user group may make an administrative policy that gives administration of the `Hardware Engineers` to a `Hardware Engineering Administrator` user group, thereby delegating administration of `Hardware Engineers` to `Hardware Engineering Administrator`. It should be noted that the right to administer an information set is separate from the right to make access policy for the information set. The fact that a user group has the right to make access policy concerning an information set does not give the user group the right to make administrative policy for the information set, and vice-versa. When an access filter 203 is first set up, a single built-in *security officer* user group has administrative authority over all of the objects in VPN 201 and over policy maker policy 306.

Inheritance with administrative policy

Inheritance works with administrative policy the same way that it does with access policy. The user groups, information sets, and available resources to which administrative policies are directed are hierarchically organized: Within the user groups, user groups that are subsets of a given user group are at the next level down in the hierarchy of user groups from the given user group. The same is the case with information sets. Inheritance applies within the hierarchy in the same fashion as with access policy. Thus, within the user

group hierarchy an administrative user who controls a user group also controls all subsidiary, contained user groups. Similarly, with the information set hierarchy an administrative user who controls the information set also controls all subsidiary, contained information sets and an administrative user who controls access policy for an information set also controls access policy for all contained information sets.

There is further a natural hierarchy of available resources. For example, one level of the hierarchy is locations. Within a given location, the servers at that location form the next level down, and within a server, the services offered by the service form the next level. The administrative user group that has control of any level of the available resources tree also controls all lower levels. For example, the administrator(s) to whom an administrative policy gives control of an access filter 203 has administrative rights to all servers beneath that site, all services running on those servers and all resources supported by those services.

Delegation: FIG. 25

Delegation is easy in VPN 201 because the members of the administrative user group that administers an object may both modify the object and make administrative policy for it. For example, if an administrative user group administers an information set, it can divide the information set into two subsets and make new administrative policies which give each of two other user groups administrative authority over one of the two subsets.

FIG. 25 gives an extended example of delegation. In FIG. 25, user groups and other objects are represented by circles; policy maker policy is represented by a square box; policy relationships are expressed by different kinds of arrows: a solid arrow for administrative policy, a dotted arrow for policy maker policy, and a dashed arrow for access policy. The part of the figure labeled 2501 shows the situation when access filter 203 is being set up: the built-in `Security Officer` user group 2503 has administrative authority over all of the built-in objects 2505 and over policy maker policy 2507. Members of `Security Officer` user group 2503 use their administrative authority to make subsets of objects 2505, rearrange the object hierarchies, and set up policy maker policy 2507.

One result of the activity of Security Officer user group 2503's activity is seen in the section of FIG. 25 labeled 2508. A member of Security Officer user group 2503 has set up an Engineering Administrators administrative user group 2509, an Engineers user group 2511, and an Engineering Data information set 2513 and has given Engineering Administrators administrative authority over Engineers and Engineering Data. The member of Security Officer has also set up policy maker policy 2507 so that Engineering Administrators has the right to make access policy for Engineering Data, as shown by dotted arrow 2510. A member of Engineering Administrators has used that right to make access policy that permits members of Engineers 2511 to access information in Engineering Data 2513, as shown by dashed arrow 2512. The member of Security Officer has thus delegated the administrative authority over Engineers 2511, Engineering Data 2513, and over access to Engineering Data to Engineering Administrators 2509.

Security Officer 2503 of course still has administrative authority over Engineering Administrators and can use that authority for further delegation. An example is shown at 2517. A member of Security Officer 2503 has divided Engineering Administrators into two subsets: Engineering Personnel Administrators (EPA) 2519 and Engineering Data Administrators (EDA) 2521. The members of these subsets inherit administrative rights over Engineers 2511 and Engineering Data 2513 from Engineering Administrators 2509. The members of EPA 2519 and EDA 2521 use these administrative rights to delegate administrative authority over Engineers 2511 to Engineering Personnel Administrators 2519 and administrative authority over Engineering Data 2513 to Engineering Data Administrators 2521. The members of EPA 2519 and EDA 2521 have further used their right to make access policy for Engineering Data 2513 to change the access policy so that access policy for Engineering Data is made by Engineering Data Administrators 2513, as shown by dotted arrow 2523, instead of by Engineering Administrators, thereby delegating that function to

Engineering Data Administrators.

Members of Engineering Personnel Administrators and Engineering Data Administrators can now use their administrative rights over Engineers, Engineering Data, and access policy for Engineering Data to refine access to Engineering Data. For example, a member of Engineering Personnel Administrators might subdivide Engineers into Software Engineers and Hardware Engineers and a member of Engineering Data Administrators might subdivide Engineering Data into Hardware Engineering Data and Software Engineering Data. That done, a member of Engineering Data Administrators might replace the access policy giving Engineers access to Engineering Data with access policies that give Software Engineers access to Software Engineering Data and Hardware Engineers access to Hardware Engineering Data.

In summary, it may be said that the administrators who have control over a user group are responsible for correctly defining membership in the user group; they may delegate any part of this responsibility to other administrators. Similarly, administrators who have control over an information set are responsible for correctly including information resources into the information set; they may delegate any part of this responsibility to other administrators. The latter administrators must of course also be administrators for some available resource from which the information being added to the information set may be obtained. Administrators of available resources carry responsibility for overall network and security operation. Likewise, they may delegate their responsibilities. Policy maker administrators, finally, hold the ultimate control over access to information. They alone may create access policies related to specific information sets. In a sense, the policy makers determine the overall information sharing policy for the enterprise. Administrators for the user groups, information sets, and available resources then determine the particulars of implementation.

Access Control using Filters 203 and Database 301: FIG. 4

As shown in FIG. 2, an access filter 203 has a position in VPN 201 which puts it between the client from which the user is requesting access to the information resource and the server upon which the information resource resides. The access filter 203 is thus able to control access by the user to the resource by interceding in the communication between a user and a service on the server which is able to provide the user with access to the information resource. In order for the user to gain access to the information resource, a session must be established between the user and the service. In the present context, the term session is defined liberally, to include well-behaved connectionless protocols. When an access filter 203 observes an attempt by a user to initiate a session with a service, it determines whether access should be permitted. It does so from the known identity of the user, the information resource to which the information is being accessed, the sensitivity level of the information, and the trust levels of the user identification, of the path between the user and the service, and of any encryption technique used.

FIG. 4 shows how a session can involve more than one access filter 203. Session 402 shown in FIG. 4 involves five access filters 203, numbered 403(1..5) in the Figure. Access filters 203 are designed such that the decision whether to grant a user access to an information resource need only be made in one of the access filters 203. The key to this feature of access filters 203 is their ability to authenticate themselves to each other. SKIP is used to do this. Every access filter 203 has an X.509 certificate that binds the access filter 203's keys to the access filter's name and is signed by the Certificate Authority for the VPN. Each access filter 203 has the names and IP addresses of all of the other access filters in VPN 201 in data base 301, and upon arrival of a session that is encrypted using SKIP, each access filter uses the Subject Name from the certificates as described above in the discussion of SKIP to determine whether SKIP-encrypted network traffic is from another access filter 203 in VPN 201.

If the access filter receiving the session is not the destination of the session, (that is, the access filter functions simply as an IP router along the path), the access filter merely verifies from data base 301 that the destination IP address is the IP address of some other

access filter 203 in VPN 201. If that is the case, then the session is allowed to pass without additional checking. When the request reaches the last access filter 203, the last access filter 203 uses SKIP to decrypt the request, to confirm that the request was indeed checked by the first access filter 203, and to confirm that the request has not been modified in transit.

Thus, in FIG. 4, access filter 403(1) uses its own copy of access control database 301 to determine whether the user who originates a session has access to the information resource specified for the session. If access filter 403(1) so determines, it authenticates the session's outgoing messages and encrypts them as required to achieve the proper trust level. Access filters 403(2..5) then permit the session to proceed because the session is from access filter 403(1) and has been encrypted with SKIP and neither decrypt the messages nor check them using their own copies of access control database 301. Access filter 403(5) then decrypts the messages, confirms that they were encrypted and therefore checked by access filter 403(1), and if the messages are intact, forwards them to server 407 that contains the desired resource. Messages in the session which pass between server 407 and user system 401 are treated in the same way, with access filter 403(5) encrypting them if necessary, access filters 403(2..4) passing them through on the basis of the authentication by 403(5), and access filter 403(1) passing the message on to system 401 on the basis of the authentication and decrypting the message if necessary.

What this technique effectively does is to make a tunnel 405 for the session between access filter 403(1) and access filter 403(5), and because of the tunnel, only the access filter 403 closest to the client needs to do decryption, access checking, and reencryption. Moreover, the tunnel is equally secure in the internal networks and in Internet 121. In a large VPN, access filter 403(1) is in the best position to check access, because it has access to the most detailed information about the user who originates the session. The technique of performing the access check at the first access filter 401 further distributes the access control responsibility evenly across the VPN, allowing it to scale to any size.

End-to-End Encryption: FIG. 5

Tunnel 405 of FIG. 4 extends only from access filter 403(1) to access filter 403(5); the messages of the session are unencrypted between system 401 employed by the user and access filter 403(1) and again between access filter 403(5) and server 407 that contains the information resource. In the case of extremely sensitive information, authentication and encryption may be needed from the near end access filter to the end of the path through the network, namely between system 403(1) and server 407.

FIG. 5 shows how this is accomplished using access filters 203. Within the VPN, authentication and encryption may be used with any client system 401 or 503 or any server system 407 in addition to access filters 203. When a client computer utilizes encryption, it uses SKIP to authenticate the session and encrypt it using a shared secret that is shared between the client computer and a selected access filter 203 and then sends the encrypted message to the selected access filter 203, thereby effectively establishing a tunnel between the client and the selected access filter 203 and making the selected access filter 203 the first access filter 203 for purposes of access checking. At the first access filter 203, the messages are decrypted and access checking is done. Since SKIP makes available the user's certificate along with the encrypted message, the user's authenticated identity can be used for access checking. If the access is permitted, the message is once again encrypted and sent to access filter 403(5) nearest server 407, which decrypts it. If data base 301 contains a SKIP name and encryption algorithms for server 407, access filter 403(5) retrieves the certificate for server 407 if necessary and uses SKIP to reencrypt the session as required for server 407. Otherwise, access filter 403(5) simply sends the message to server 407 in the clear. If the message was reencrypted for server 407, server 407, finally, receives the encrypted message and decrypts it. The access filters 203 intermediate to the first access filter 203 and last access filter 203 simply note that the message is from another access filter and is encrypted with SKIP and pass the message on, as described above. When server 407 retrieves the information resource, it either sends it in the clear to access filter 403(5) or encrypts the message containing the resource with the key for access filter 403(5). The process of decrypting and encrypting described above is then performed in reverse, pairwise, from server 407 to access filter 403(5), from access

filter 403(5) to access filter 403(1), and finally from access filter 403(1) to the original client system, which decrypts it.

The effect of this technique is to construct a tunnel on the path between the client and the server which runs from the access filter 203 on the path which is nearest to the client to the access filter 203 on the path which is nearest to the server. If the client is capable of encryption and decryption, the tunnel can be extended from the access filter nearest the client to the client and if the server is capable of encryption and decryption, the tunnel can be similarly extended to from the access filter nearest the server to the server. Once the first access filter 203 in the path has been reached and has authenticated the session, no further encryption or decryption is required until the access filter 203 nearest the server has been reached. Moreover, access control database 301 in each access filter 203 contains all of the necessary identification and certification information for the client, the server, and the access filters 203 in the route. An advantage of the end-to-end encryption technique just described is that it distributes encryption load throughout the network, rather than concentrating it at the access filters connecting the VPN to the Internet, and thereby enhances scalability.

FIG. 5 shows how the technique works with a session 501 that originates with a *roamer*, that is, a client 503 whose connection to the VPN is via Internet 121. Roamer 503 is equipped with SKIP, as is target server 407 on an internal network. When SKIP was configured in the roamer, it was given the certificate for access filter 403(3) and access filter 403(3) was given the certificate for the roamer. When roamer 503 sends a message belonging to the session, it addresses the message to server 407 and encrypts it using a transport key which it shares with access filter 403(3). The message is thus tunneled via tunnel 505 to access filter 403(3). There, access filter 403(3) decrypts the session, performs the access check, and reencrypts it using a transport key for access filter 403(5). The subsequent access filters 403 in the path allow the session through because it is authenticated by access filter 403(3), thus providing tunnel 507 to at least access filter 403(5). If target server 407 is SKIP-equipped, access filter 403(5) extends the tunnel to target server 407, as described above.

Adaptive Encryption and Authentication based on Data Sensitivity: FIGs. 6 and 7

An important task in access control in a VPN is determining the minimum amount of security needed by a session. This is important first because at least that minimum must be guaranteed and second because more security than is necessary wastes resources. The techniques employed in access filters 203 to determine the minimum amount are collectively termed SEND (Secure Encrypted Network Delivery). In SEND, access control database 301 contains a data sensitivity level for each information resource. The data sensitivity level indicates the level of secrecy associated with the information resource and is assigned to the information resource by the security administrator responsible for the resource. An exemplary set of levels is Top Secret, Secret, Private, and Public.

The levels used to indicate data sensitivity are also used to indicate the trust level required for the access request. As previously described, access will be permitted only if the trust level determined from the trust level of the technique used to identify the user, the trust level of the path of the access request through VPN 201 or the trust level of any encryption technique used to encrypt messages sent over the path is at least as great as the data sensitivity level for the information. The trust levels for user identifications, paths, and encryption algorithms are contained in access control database 301. With regard to trust levels of paths, the VPN is divided into *network components*, each network component being a connected set of IP networks that is separated from other components by access filters 203. Each network component has a name and a trust level. For example, an Internet component will have the Public trust level, while an internal network component may have the Private trust level. The trust level of a given component may be based on its physical security or on the use of encryption hardware in the component. As each access filter 203 is added to a VPN, a description of its connections to the components of the VPN is added to database 301. Included in this description are the trust levels of the networks. Consequently, any access filter 203 can use its copy of database 301 to determine the trust level of each component of the path by which a session will be carried between a client and a server.

The trust level for a user is determined from the manner in which the access request

identifies the user. In access control database 301, each group of users has one or more identification techniques associated with it, and each identification technique has a minimum trust level. The basic techniques are:

- **Certificate via SKIP.** A user is identified by the name in his or her X.509 certificate used with the SKIP protocol to authenticate and encrypt traffic.
- **Certificate via User Identification Client.** A user is identified by the name in his or her X.509 certificate transmitted to attached access filters 203 via a special Conclave client module called the User Identification Client. This transmittal is done securely, using a challenge/response mechanism.
- **Windows Domain ID via User Identification Client.** A user who logs in to a Microsoft Windows Domain and has installed the User Identification Client automatically has his or her Windows identity, including group memberships, transmitted to attached access filters 203. The logon to the network is done securely within the mechanisms of the NetBIOS protocol.
- **Authentication Tokens.** Authentication tokens (such as those manufactured by Security Dynamics Inc. and Axent Corp.) may be utilized in two ways: via the User Identification Client in an out-of-band manner, or in-band within the Telnet and FTP protocols.
- **IP Address and/or Domain Name.** The IP address or fully qualified domain name of the user's computer.

In a preferred implementation of SEND, the identification techniques have a predetermined order from most secure to least secure. The techniques just listed would be ordered are as they are in the above list, with the most secure techniques being at the top of the list. The ordering of the identification techniques is somewhat subjective, but reflects the general security of the identification technique and the rigor applied to the distribution and validation of user identities. An administrator in VPN 201 then relates the ordered trust levels to the ordered identification techniques. For example, if the administrator relates the *private* trust level to identification by means of authentication tokens, a user who desires to access a resource with the *private* sensitivity level must identify himself or herself by means of an authentication token or another identification technique which is above the authentication in the order of identification techniques. The administrator of the access

filter likewise orders the cryptographic algorithms available in the VPN from most secure to least secure and relates the ordered trust levels to the ordered cryptographic algorithms and orders the network paths employed in VPN 201 and relates the ordered trust levels to the ordered network paths. These relationships between trust levels and orderings with regard to security are included in access control database 301. Then a SEND table is constructed which relates trust and sensitivity levels to identification and encryption techniques. FIG. 6 is a conceptual representation of such a SEND table.

SEND table 601 has three columns: one, 603 for the trust/sensitivity levels, one, 605, for minimum encryption methods, and one, 607, for minimum identification methods. For details on the encryption methods of column 605, see Bruce Schneier, *Applied Cryptography*, John Wiley & Sons, New York, 1994. Each row 609 of the table associates a trust/sensitivity level with a minimum encryption level for the path connecting the access filter, client, and server and a minimum identification level for the user. Thus, row 609(1) associates the "top secret" trust/sensitivity level with the 3DES encryption algorithm and a user certificate obtained via SKIP. A user who wishes to gain access to a resource with the sensitivity level "top secret" must consequently have an identification that is certified by SKIP and if the path does not have a "top secret" trust level, the session must be encrypted with the 3DES algorithm. On the other hand, as shown by row 609(4), a user who wishes to gain access to a resource with the sensitivity level "public" may be identified by any method and there is no requirement that the session be encrypted.

When a new session is initiated, the first access filter 203 in the path employed for the session proceeds as follows:

1. The access filter determines the information resource being accessed and looks up its sensitivity level in database 301.
2. The minimum authentication for that sensitivity level from SEND table 601 specifies which identification mechanisms may be used by the access filter to identify and authenticate the user making the access.
3. The first access filter 203 then consults database 301 to determine from the user groups the user belongs to and the information sets the resource belongs to

whether the user may access the resource.

a. The first step is to determine from the access data base which of the identification methods used to identify the user have trust levels high enough for the sensitivity level of the resource.

b. Then first access filter 203 consults database 301 using the user's identification according to each of the identification methods that has a high enough trust level to determine the user groups that the user belongs to.

c. First access filter 203 also consults data base 301 to determine which information sets the resource belongs to.

d. Having determined the relevant user groups and information sets, first access filter 203 consults data base 301 to locate the access policies that determine whether access is to be allowed or denied to the session. If at least one policy allowing access is found and none denying access are found, the user is allowed access; otherwise, access is denied. Details of steps b, c, and d will be given below.

4. If access was not denied, the first access filter 203 then consults database 301 to determine the network components that make up the route through the VPN from the client to the server that contains the information resource. The route is considered as having up to three logical segments:

a. Segment (a), from the client to the first access filter 203. This segment may or may not have been encrypted, depending upon whether the client uses SKIP.

b. Segment (b), from the first access filter 203 to the access filter 203 in the path nearest the server; and

c. Segment (c), from the access filter 203 nearest the server to the server; this segment also may or may not be encrypted.

If segment (a) and segment (c) exist, each will consist of a single network component. Segment (a) will not exist if the client is on the first access filter; segment (c) will not exist if the server is on the access filter nearest the server. If segment (b) exists, it will consist of one or more network components. Segment

(b) will not exist if there is only one access filter between the client and server.

5. For each of the segments:

a. For segment (a), any encryption must be done by the client. If the trust level of segment(a) is not at least as strong as the sensitivity of he resource, or if the trust level of the encryption done by the client is not at least as strong as the sensitivity of the resource, access is denied.

b. For segment (b), if the weakest trust level of any network component in the path is greater than or equal to the data sensitivity of the resource, then the traffic is sent without encryption. This corresponds to the case where the network is inherently secure enough to transmit the data. In the example table above, information resources with a Public data sensitivity level may be transmitted on any network, as shown by row 609(4). However, the access filters 203 will use SKIP to authenticate the session, allowing subsequent access filters to pass the session through without incurring the larger overheads of decryption, access checking, and reencryption. If the weakest trust level for the path is less than the data sensitivity of the resource, then the SEND table is consulted for the minimum encryption algorithm required for the sensitivity level and the session is encrypted using that algorithm. The encryption upgrades the security of the link, making it suitable to carry data of that given sensitivity and permitting access by the user to the resource.

c. For segment (c), the portion of the path from the access filter 203 nearest the server to the server, first access filter 203 determines the trust levels of segment (c) and of any encryption used in segment (c) from information in database 301. If the trust level of this segment of the path is less than the sensitivity level of the information resource, and in that case, if the encryption used in segment(c) is not at least as strong as that required as the minimum level in the SEND table considering the sensitivity level of the resource, then first access filter 203 will deny access.

The above method of determining sensitivity and trust levels ensures that access filters 203 employ encryption only as necessary to achieve the necessary trust levels. This reduces the

number of sessions that will be encrypted while keeping the description of network configuration in database 301 simple and manageable. The result is better scalability with regard to both management of and performance in the VPN.

FIG. 7 provides an example of how the sensitivity level of an information resource, the trust level of the user identification, and the trust level associated with the path between the client and the server affect access by the user to the information resource. In FIG. 7, a SKIP-equipped user at client 703 initiates a session 701 to obtain an information resource 723 which is stored at SKIP-equipped server 705. Segment (a) of the above discussion appears in FIG. 7 at 707; segment (b) appears at 709(1..4); Segment (c) appears at 711. Information resource 723 has a sensitivity level of "secret". The first access filter 203 that the session encounters is filter 203(1). Access filter 203(1) uses its copy of the access control database to determine the sensitivity level of resource 723. Here, the user has used a SKIP certificate and an examination of SEND table 601 in data base 301 shows access filter 203(1) that this kind of user identification meets the requirements for information resources having the "secret" sensitivity level, so segment (a) 707 has the required trust level. Consequently, the first access filter goes on to determine the trust level of segments (b) 709(1..4) and (c) between access filter 203(1) and server 705 in the VPN. Segment 709 has subsegments 709(1), 709(2), 709(3), 709(4), and 709(5), and first access filter 203(1) checks the trust level of each of these subsegments in database 301. Segment 709(2) is Internet 121, so its trust level is "public", which is the minimum in segment 709. Then access filter 203(1) uses access control data base 301 to check the trust level of segment 711. It is "secret". Thus, only segment (b) 709 has a trust level that is too low for the path of a session that is accessing a "secret" information resource 703. To deal with this problem, access filter 103(1) must encrypt the session to bring it up to the necessary trust level. First access filter 203(1) consults SEND table 601 to determine what kind of encryption is required, and row 609(2) indicates that DES encryption is sufficient. First access filter 203(1) accordingly encrypts the session using that algorithm and sends it to access filter 203(5).

In FIG. 7, segment 707 connecting client 703 to access filter 203(1) has a trust level which

is high enough for the resource's sensitivity level, and there is thus no need for client 703 to encrypt its request. When that is not the case, access filter 203(1) will give client 703 access only if client 703 has encrypted the request using an encryption method whose trust level is sufficient for the sensitivity level of the resource. It is for this reason that roamer 503 in FIG. 5 must be SKIP-equipped. Since roamer 503 accesses access filter 403(3) via Internet 121, roamer 503's requests can never have more than the *public* trust level unless they are encrypted, and in order to have full access to the resources in VPN 201, roamer 503 must use an encryption method such as the one provided by SKIP whose trust level is sufficient for the highest sensitivity levels. In some embodiments of access filter 203, the access filter may negotiate the encryption technique to be used in a request with the client in a manner similar to that which it employs in the preferred embodiment to negotiate the user identification mode.

Overview of the Administrators' Interface to Access Control Database 301: FIGs. 8-12

An access policy defines access in terms of user groups and information sets; consequently, before an access policy may be defined, the administrators must define the user groups and information sets; how that is done is shown in FIG. 8. Defining a user group involves steps 803 through 807: first the users are defined, then the user groups are defined, and then the users are assigned to the proper user groups. Defining information sets involves steps 809 through 813: first the resources are defined, then the information sets are defined, and then the resources are assigned to the information sets. When this has been done for the user group and information set involved in a policy, the access policy can be created, as shown at 815. As previously pointed out, the rights to define and determine the membership of user groups and information sets and to make administrative policy for them are determined by the administrative policy, while the right to make access policy for user groups and information sets are determined by the policy maker policy.

As can be seen from the foregoing, the user interface is generally used to define relationships between two entities or sets thereof. The general form of the graphical user interface (GUI) for access control database 301 corresponds to that task. The display

includes two windows, each of which contains representations of entities that are to be brought into relationship with each other, and the relationship is defined by selecting the entities and where necessary, defining the relationship.

Defining User Groups: FIG. 9

FIG. 9 shows the display 901 for populating and defining user groups. Window 903 in the display contains a hierarchical display of currently-defined user groups; window 903 is similar to those used to display hierarchies of files in the Windows 95 brand operating system manufactured by Microsoft Corporation. In window 903, user groups for which the administrative user using display 901 has administrative rights appear in black; the other user groups appear in gray. Above the two windows are two button bars 911 and 915. Button bar 911 lists the displays available for modifying access control database 301, while button bar 915 lists the operations that may be performed on those displays. Thus, the button label "user groups" in button bar 911 is highlighted, indicating that display 901 is the one for populating and defining user groups. With regard to button bar 915, when window 903 is active, an administrative user with the right to administer a user group may modify the user group by selecting it in window 903 and using the *delete* button in button bar 915 to delete the user group or the *new* button to add and name a new user group that is beneath the selected user group in the hierarchy. When the administrative user clicks on *apply* button 921, access filter 203 modifies its copy of access control database 301 to conform with what is on display 901 and the modifications are propagated to all copies of access control database 301 in the VPN.

Window 909 displays users. A set of user is indicated in the display by the manner in which the user in the set identified. In this case, the users are identified by IP addresses and they appear in the display as ranges of IP addresses. Button bar 913 indicates the other kinds of identifications that can be displayed in window 909. As with window 903, when the window is active, the *new* and *delete* buttons can be used to add and delete users. To assign the user(s) specified by a user identification to a user group, the user of the GUI selects a user group, as shown at 917, and a set of identifications, as shown at 919, and then uses the *add to group* button in button bar 913 to add the set of identifications to the group, as

is shown by the fact that the range of IP addresses selected at 919 now appears in the hierarchy below the user group selected at 917. The effect of the operation is to make users whose sessions have the source IP addresses listed at 917 into members of the user group *R&D*, and when the user clicks on the *apply* button, all copies of access control database 301 are modified accordingly.

FIG. 10 shows the display 1001 used to define information sets. Here, window 1003 contains a hierarchical list of information sets and window 1005 contains a hierarchical list of the available resources. The hierarchical list of information sets and the hierarchical list of available user groups made in the same fashion as the list of user groups. Again, information sets and available resources over which the user of display 1001 has administrative authority appear in black; the other items on the list appear in gray. In window 1001, the available resources are the Internet and the two locations that make up VPN 201. In a more developed VPN 201, the list of available resources would indicate servers at the location, services in the servers, and the information items provided by the services. For example, if the service provides a directory tree, the information items contained in the directory tree would be indicated by means of a pathname which specified the root of the directory tree and used wildcard characters to specify the files above the root in the tree. When a resource is added to a server, the resource may be defined via the 1005 window. Having thus been defined, a resource may be assigned to an information set in the same fashion that a user identification is assigned to a user group. Again, clicking on the *apply* button causes the changes in display 1001 to be propagated to all copies of access control database 301.

FIG. 11 shows the display 1101 used to define policies. Which type of policy is being defined is specified in button bar 1113; as indicated there, display 1101 is defining access policy. All of the policy displays have the same general format: a window 1103 which contains a hierarchical display of user groups, a window 1105 which contains a display of a hierarchy of objects for which policy may be defined and a policy definition window 1107 which contains access policy definitions 1108. In the hierarchy of objects, objects for which the user of display 1101 has the right to define policies appear in black; the others

appear in gray. In display 1101, what is being defined is access policies, so the objects are information sets.

Each access policy definition has four parts:

- an active check box 1117 that indicates whether the access policy defined by the definition is active, i.e., being used to control access;
- the user group 1119 for which the access policy is being defined;
- the information set 1123 for which the access policy is being defined; and
- *access* field 1121, which indicates whether access is being allowed or denied and thereby defines the access policy.

Menu bar 1109 and button bar 1115 permit administrators whom the policy maker policy allows to do so to edit, add, delete, and activate or deactivate a selected policy definition 108. Active check box 1117 of each policy definition 1108 permits the administrator to activate or deactivate the selected policy definition 1108; access field 1121 permits the administrator to select either *allow* or *deny* as the policy. The *delete* button in button bar 1115 permits the administrator to delete a selected policy; the *new* button permits the administrator to make a new policy definition 1108; to do this, the administrator selects a user group in window 1103 and an information set in window 1105 and then pushes the *new* button. The new access policy definition 1108 appears in display 1107, and the administrator can edit the new access policy definition as just described. To apply a change to access control database 301 and propagate it to all access filters 203, the administrator clicks on *apply* button 1125.

Display 1101 also contains a policy evaluator tool which lets the administrator see how the current set of access policy definitions determines access for a given user group or resource set. When the administrator clicks on the *policy evaluation* button in button bar 1113 and selects a user group from display 1103, the tool displays the selected user group in blue and all of the information sets in display 1105 which the policy definitions permit the user group to access in green and the remainder in red; all of the policy definitions which are relevant to the determination of which information sets may be accessed by the user group are highlighted in the same set of colors. The same thing happens if the administrator selects an

information set; then the evaluator tool displays the selected information set in blue, all of the user groups that can access the information set in green and the rest in red, and also highlights the relevant policy definitions. The user can also select a policy. In that case, the selected policy appears in blue and the user groups and information sets affected by the policy in appear in blue or red, as determined by the policy. The user can additionally select more than one user group, information set, or policy. In that case, the evaluator tool shows *each* policy that applies to *all* of the selected items and the effects of those policies. The evaluator tool can be turned off by clicking on *policy evaluation* in button bar 1113 and colors and highlights can be turned off in preparation for a new policy evaluation by clicking on the *reset evaluation* button in button bar 1115.

FIG. 12 shows the display 1201 used to input information about an access filter 203 to access control database 301. Window 1203 shows a hierarchical list of the access filters 203; when the window is active, access filters may be added or deleted using the *add* and *delete* buttons in button bar 1209. Window 1205 is used to input or display information about the access filter 203. The display in window 1207 is determined by clicking on a button in button bar 1207; as shown by the buttons, displays in window 1207 can be used to input and view information about access filter 203's network connections, to input and view information about the trust levels of those connections, to scan networks for available servers and services, to set up alerts for problems detected in access filter 203, to specify optional parameter for software, and to specify the distribution order of access control database 301 changes. The highlighting of *alert setup* indicates that display 1205 shown in FIG. 12 is the display used to display and establish alerts.

User Interface for Discovering Resources: FIGs. 18 and 24

The users of VPN 201 have an interface for seeing what resources are available to them in VPN 201. The interface, termed herein the *IntraMap* interface (*IntraMap* is a trademark of Internet Dynamics, Incorporated), shows each user at least the resources that belong to the information sets that the user may access according to the access policies for the user sets the user belongs to. In other embodiments, the IntraMap may take the sensitivity level of the resource and the trust level of the user's identification into account as well.

The IntraMap interface is implemented by means of a Java™ applet that runs on any Java-equipped World Wide Web browser. Using the Web browser, the user can scan the graphical display to find and access resources that are available to the user or to request access to resources that are not currently available to the user. Access by a user to a resource is determined by the access policies that apply to the user and the resource. FIG. 18 shows the display 1801 produced by the IntraMap interface. The left-hand side of IntraMap display 1801 shows a Resource List 1803; the right-hand side of the display shows a Find field 1807, a Sort section 1809, a Services section 1811, and a Description field 1813. On-line help for using the IntraMap is available by clicking Help button 1815.

Resource List 1803 shows resources and information available in VPN 201 to the user who is using the IntraMap interface. The listing is hierarchical. The user can expand or collapse branches of the "tree" by clicking on the '+' and '-' markers on the branches. Each entry 1804 in the list includes a name for the resource. The color used to display an entry indicates what kind of access the user has. If the entry 1804 is displayed in blue, the user has an active hyperlink to the resource and may double click on the resource to have it displayed. If it is displayed in black, it is also available to the user, but no hyperlink is available, so a separate application must be used to retrieve it. Resources displayed in gray are not directly available to the user, but if the user selects one, the IntraMap interface opens a dialog box that permits the user to send email requesting access to the administrator who is responsible for access policy for the information set the resource belongs to. The administrator may then modify the access and/or administrative policies as required to give the user access. An administrator may further give a resource the *hidden* property. When a resource has that property, it will appear in IntraMap interface 1801 only if the user belongs to a user group that the access policies permit to have access to an information set that the resource belongs to. If a resource does not have the *hidden* property, it will always appear in IntraMap interface 1801. Otherwise, it does not appear. A resource may have a more detailed description than that contained in its entry 1804. The description is displayed in Description field 1813 when the user selects the resource.

In addition to resource list 1803, IntraMap display 1801 displays two specialized resource lists at 1805.

- What's New 1806 displays the latest information postings from others within the enterprise. If an administrator has given the user access to the What's New web page, the user may post the URL of a new resource there.
- What's Hot 1808 displays the enterprise's most popular information resources, based on how frequently they are accessed.

The service types control at 1811 lets the user filter the resources that are to be displayed in resource list 1803 by the type of service that provides the resource. Each service type has a check box in service type control 1811. If the box is checked, the service type is included and the resources associated with this service appear in the Resource List. Otherwise, the resources associated
with this service do not appear in the Resource List.

The IntraMap interface lets the user sort Resource List 1803 by information sets, locations, or services. To do this, the user selects the way he or she wishes to sort the resource list in sort field 1809. The user may also specify the order in which the categories are used in the sort. The interface further has a search function. To do a search, the user enters a search string in FIND field 1807. The resource list and the resource descriptions for the resources on it are then searched in the order specified in sort field 1809. The search simply looks for whole or partial word matches. It is not case sensitive. The first match is displayed, and function keys may be used to navigate to other matches. Of course, if a user has not checked a service type in service type field 1811, resources of that service type are not involved in either sorting or searching.

Fig. 24 shows an implementation 2401 of the IntraMap interface. To the user of VPN 201, the IntraMap interface appears as a Web page that is one of the resources provided by report manager 209 running on access filter 203(c) of FIG. 2. A user in VPN 201 or even the general public (that is, someone who is a member of the Internet user group) may be given access to the IntraMap interface in the same fashion as he or she may be given access

to any other resource. As will be clear from the following description, the Web page for the IntraMap may be on any server in VPN 201. Implementation 2401 has components in workstation 2403 used by the user to look at the IntraMap, components in access filter 203(I) which is local to work station 2401, and in access filter 203(c), which is the access filter upon which report manager 201 runs. Of course, access filter 203(c) may also function as a local access filter. Local access filter 203(I) is connected to report access filter 203(c) by VPN 201 and workstation 2403 is connected to local access filter 203(I) by LAN 213.

As will be explained in more detail later, all access filters 203 have a layered architecture. The bottommost layer is an Internet packet filter 2419 that deals only with Internet packet headers. Packet filter 219 reads the source and destination addresses in the Internet packet headers and applies a set of rules to them. As determined by the rules, it either accepts them, discards them, or routes them further in VPN 201. The rules also determine how the accepted packets are to be routed within access filter 203. The next layer of the architecture is service proxies 2427. The service proxies intercept traffic for services such as the World Wide Web and do access checking on the traffic. If access filter 203 provides the service itself or does access checking for a server that provides the service, IP filter 2419 sends packets intended for the service to a service proxy 2427 for the service. The service proxy uses access control database 301 to do protocol-level access checking for the service. For example, the service proxy for the Web service may check whether the user making a request for a given Web page has access rights for the page. The next higher level is services level 2425; if the relevant service proxy permits an access request and the access filter is also the server for the service, the request goes to the service at service level 2425 to be processed. In the case of the Web page, the service would locate the page and return it to the requestor. Two services are involved in the IntraMap: the Web service and an IntraMap service. In FIG. 2401, the Web service appears as WebS 2423. The proxy for WebS 2423 is WebP 2421; for reasons that will become clear in the following, the IntraMap service has only a proxy, IntraMapP 2417. Additionally, access control database 301 includes IntraMap information 2422, which is an optimized version of the information in access control data base 301 that serves as a basis for the IntraMap display.

The chief difference with regard to the IntraMap implementation between access filter 203(c) and access filter 203(I) is that access filter 203(c) includes a World Wide Web page 2410 with a copy of IntraMap Java applet 2411. When downloaded from access filter 203(I) to Web client 2429 in work station 2403, Java applet 2411 produces requests directed to IntraMap server 2425 and uses the results returned by IntraMap server 2425 to produce IntraMap display 1801.

Operation is as follows: to the user of work station 2403, the IntraMap may appear as a link to a Web page. Thus, to use the IntraMap, the user activates a link to IntraMap page 2410. Web browser 2429 in workstation 2403 responds to the activation of the link as it would to the activation of any other link to a Web page: it makes a request for the page and sends it to the server indicated in the link. In the case of the link to the IntraMap, the link specifies Web server 2423 in access filter 203(c), so the request goes via local access filter 203(I) and VPN 201 to access filter 203(c). As with any other access to a resource in VP 201, local access filter 203(I) does access checking for the IntraMap page request. Since the request is for a Web page, the checking is done by Web proxy 2421. In most VPNs 201, IntraMap page 2410 will be accessible to any user in VPN 201, and access control data base 301 thus indicates that any user with a valid IP source address may access IntraMap page 2410.

When the request is received in access filter 203(c), IP filter 2419 forwards it to Web proxy 2421, which in turn forwards it to Web server 2423, which responds to the request by downloading IntraMap applet 2411 to Web browser 2429 in work station 2403, where IntraMap applet 2411 begins executing in Web browser 2429. During execution, it sends a request to IntraMap proxy 2427 for IntraMap information 2422. Like all Java applets, IntraMap applet 2411 sends the request to the server that it is resident on, in this case, access filter 203(c). However, as with any other request from workstation 2403, the request goes by way of local access filter 203(I). There, IntraMap proxy 2427 detects that the request is addressed to IntraMap proxy 2427 in access filter 203(c) and instead of sending the request on to access filter 203(c), obtains IntraMap information 2422 from the local copy of access control data base 301 in local access filter 203(I), filters it so that it

specifies only those resources belonging to the information sets to which the user groups to which the user belongs have access to make to list 2431 and returns it via LAN 213 to IntraMap applet 2411, which then uses list 2431 to make IntraMap display 1801. In making the display, applet 2411 applies any filters specified in the request and also sorts the list as specified in the request. List 2431 not only indicates the resources that are available, but also contains information needed to fetch the resource. Thus, if the resource has a hyperlink, the hyperlink is included in the list; if it is a resource for which the user presently does not have access, but to which the user may request access, the list includes the name and email address of the administrator for the resource.

Details of Access Control Database 301: FIGs: 13-17

In a preferred embodiment of access filter 203, access control database 301 is implemented at two levels: one used by the graphical user interfaces use to manipulate access control database 301 and another used in actual access checking. The first level is implemented using the Microsoft Jet brand database system developed by Microsoft Corporation. The second is implemented using memory mapped files (MMFs) which are compiled from the first-level data base. The following discussion will describe the first-level implementation and explain how the information contained in it is used in access checking. In reading this discussion, it should be remembered that actual access checking is done using the MMFs, as will be described in detail later.

As is the case with most database systems, the Microsoft Jet brand database system has a *schema*, that is, a description of the logical structure of the database. FIGs. 13-17 are displays generated by the Microsoft Jet brand database system of the schema for access control database 301. FIG. 13 shows the schema 1301 for the part of the database that defines user groups. The display is made up of two elements: representations of *classes of tables* 1303 in the database and representations of *links* 1305, which show relationships between tables belonging to certain classes of tables. The representation of the class of the table shows the name of the class at 1310 and the data fields that will be contained in each table belonging to the class at 1308. Each table instance has an ID assigned by the database system. The other data in the table varies with the class of table. A link is made

between a first table belonging to the first class of tables and a second table belonging to the second class of tables by using the ID of the second table in the first table and vice-versa. Thus, link 1305 shows that tables of the class *User Group Tree* table 1307 can be linked with tables of the class *User Groups* table 1309. Some links have numbers at their ends. The numbers indicate the number of the links that the table at the end the number is located at may have. Thus, the link connecting the table of class 1309 and the table of class 1307 has the number *1* at the end for the table of class 1309 and the number ∞ at the end for the table of class 1307, indicating that any number of IDs of instances of class 1309 may appear in an instance of class 1307, but only one ID of an instance of class 1307 may appear in an instance of class 1309.

User Group Tables: FIG. 13

User group tables 1301 contains a table of class user groups 1309 for each user group in database 301. Data of particular interest in tables of class *User Groups* 1309 include the group name, which is the character-string name of the group, the group description, which is a character-string description of the group, and pre-defined information, which indicates among other things whether a user who is a member of the group is an *administrator*, i.e., can make administrative policy, a *security officer*, i.e., can make policy maker policy, or a simple user of information. User group tables 1301 further organizes the user groups into a hierarchy – both for the purposes of inheritance and also for the hierarchical display of user groups shown in window 903 of FIG. 9, associate identifications of users with the user groups, and associate alerts with the user groups. The organization into the hierarchy list is done by means of tables of class *User Group Tree* 1307. Each table of the class *User Group Tree* links a table of the class *User Group* to a parent user group (also of the type *User Group*). Multiple *User Group Tree* tables may exist for a particular *User Group* table, depending on the number of places in which a particular user group appears.

As already mentioned, there are five different ways of identifying users to an access filter 203: by a range of IP addresses, by a fully-qualified Internet domain name, by the identity of the user in the Microsoft Windows brand operating system, by an authentication token, and by certificate. The table classes for the tables used to identify users by certificates are

shown as 1321. The table classes for the tables that identify users by a range of IP addresses are shown at 1317; those for the tables that identify users by IP domains are shown at 1319; those for the tables that identify users by Windows brand operating system ID's are shown at 1315; and those for the tables that identify users by authentication tokens (labeled as smart card in the figure) are shown at 1323. The table classes 1325, finally, define tables for the information used in alerts that are related to user groups. A table of *User Group* class 1309 may have associated with it any number of tables for any of the ways of identifying users. As this implies, a given user may be identified in a number of different ways at once.

In order to perform an access check, access filter 203 must determine what user groups the user making the request belongs to. The request includes an identification for the user, and the identification is the starting point for the determination. The tables in user group tables 1301 permit access filter 203 to determine from the identification what user groups the user belongs to and from those user groups, the hierarchical relations that determine the other user groups the user belongs to. Assuming that the user is identified by an IP address, access filter 203 begins by finding one or more tables of the *IP Range Definition* class (in 1317) which define ranges of IP addresses which include the user's IP address. Each of these tables has a link to a table of the *IP Ranges* class (in 1317) which relates the range defined in the *IP Range Definition* class table to a user group ID, which in turn serves as a link to a table of class *User Groups* 1309 for the user group corresponding to the range of IP addresses. Each of the tables of class *User Group* has a link to a table of class *User Group Trees*, from which links can be followed to the tables of class *User Groups* for the user groups from which the user groups specified by the IP addresses inherit access rights. Thus, at the end of the process, IP filter 203 has located all of the user groups which are relevant for determining whether the user may access the resource. Moreover, IP filter 203 knows from the request how the user is identified and can determine from that what level should be assigned to the identification of the user used in the request. The information in user group tables 1301 is compiled into MMFs. When a user initiates a session, the user provides a user identification to the first access filter 203 on the session's path; access filter 203 uses the user identification with the MMFs to make a determination

equivalent to the one explained above. Access filter 203 can thus determine for a given user identification whether it identifies a user that has access, what kind of user identification it is, and therefore what trust level it has, and which user groups the user belongs to. User group tables 1301 thus contain all of the information needed for the user portion of an access policy 1108.

Information Set Tables: FIG. 14

FIG. 14 shows the schema 1401 for the tables that define information sets. These tables relate information sets (*resource groups* in FIG. 14) to the resources that make them up and to the network locations of the resources and also organize the information sets into the hierarchical list of information sets displayed at 1003 of FIG. 10. Each information set in access control database 301 is represented by a table of class *resource group* 1403. Tables of class *resource group* are organized into a hierarchy for inheritance and display purposes by tables 1419. The relationship between an information set and the resources that make it up on one hand and the locations in the VPN in which they are stored are established by tables of class *resource group elements* 1407. A table of class *resource group* may be linked to any number of tables of class *resource group elements.* A table of class *resource group elements* is linked to any number of tables of the classes *Site Elements* 1411, *Services* 1413, and *Resources* 1409. There is a table of class *Resources* for every resource represented in database 301. Included in the table are the resource's ID, its name, the ID for the service that provides it, an ID for a definition of the resource's sensitivity level, a description of the resource, the email address of the administrator of the resource and a *hidden* flag which indicates whether IntraMap should display the resource to users who do not belong to user groups that have access to the resource. The IntraMap interface obtains the information it needs about a resource from the *Resources* table for the resource.

The tables of the classes *Site Elements* and *Services,* as well as those of the classes *Sites* 1415 and *Servers* 1417 belong to the classes 1421 that describe the locations of information in the VPN. There is a table of class *Sites* for every physical location in the VPN; there is a table of class *Servers* for every server in the VPN; and there is a table of

class *Services* for every service in the VPN. Links in the tables of class *Site Elements* relate sites to servers; links in the tables of class *Servers* relate the servers to the services they offer; and links in the tables of class *Services* relate the services to the resources that they host.

In determining what information sets a requested resource belongs to, access filter 203 begins with the information in the request. The request is contained in an IP packet, and consequently has a header and a body. In the header there is an IP address which specifies a location in virtual network 201 and a server at the location, a port number which specifies a service on the server, and in the body, the description of the resource in the form prescribed by the protocol. For example, if the request is for a Web page, the description of the resource will be the resource's URL. Access filter 203 uses the IP address to locate a table of class *Sites* , uses the link in that table to locate a table of class *Site Elements* 1411. That table relates the site to the server IDS for the servers at the site and access filter 203 uses the server IDS to locate the tables of class *Servers* 1417 for the site's servers. It can then use the IP address again to locate the table of class *Servers* corresponding to the server specified in the request and can follow the links from the *Server* table to the tables of class *Services* for the service and can use the port number from the request to find the proper *Service* table. Once it has found the proper *Service* table, it can follow the links to the tables of class *Resources* 1409 and locate the *Resources* table corresponding to the resource in the request. From there, there is a link to a table of class *Resource Group Elements* 1407 which relates resources to the resource group identifiers for the information sets they belong to. The resource group identifiers in turn specify tables of class *Resources Group* 1403, and these tables have links to tables of class *Resource group Tree*, from which the hierarchies of resource groups can be determined to which the resource specified in the request belongs. Having done that, access filter 203 has found the resource groups that are relevant for determining whether the request should be granted. *Resources* table for the resource further contains the sensitivity level for the resource. Again, the information in information set tables 1401 is compiled into MMFs. When the request reaches the first access filter 203 in the path between the user and the server that provides the resource, the first access filter 203 uses the MMF files to make a

determination that is the logical equivalent of the one just described. Thus, after examining the MMF files that contain the information from User Groups tables 1301 and Information Sets Tables 1401, the proxy has determined the trust level of the user identification, the sensitivity level of the information resource, the user groups the user belongs to, and the information sets the information resource belongs to.

Policy Tables: FIG. 16

FIG. 16 shows the tables used in access control database 301 to define access control policies; included in these policies are access policies, administrative policies, and policy maker policies:

- Access policies relate user groups to resource groups;
- Administrative policies relates a user group whose members are administrators to *one* of:
  - d. another user group
  - e. an information set
  - f. a resource
  - g. a location (site) in the VPN
  - h. an access filter 203 or other server
  - i. a service
- Policy maker policies relate user groups of administrators to information sets.

Each policy relates a *left-hand side*, which is always a table of class *User Groups* 1309, to a *right-hand* side, which, depending on the kind of policy, may be a table of class *Resources* 1409, a table of class *Resource Groups* 1403 (representing information sets), a table of class *Sites* 1415, a table of class *Services* 1413, a table of class *Servers* 1417, or a table of class *User Groups* 1309. Policy tables 1601 thus fall into three large groups: left-hand tables 1603, policy tables 1605, and right-hand tables 1609. The right to change policies is hierarchical: a member of a user group whose *User Group* table indicates that it is a group of a type of *Administrators* can change access policies as determined by the administrative policy for the group. In turn, those administrators may specify other administrative policies related to their sub-domain.

Corresponding to the three kinds of policies, there are three classes of tables in policy tables 1605: tables belonging to *Policies Access* class 1611, *Policies Administer* class 1613, and *Policies Policy Maker* class 1619. Tables of all of these classes share a number of features: they contain the ID of the user group table for the left-hand side of the policy, the ID for the table representing the item specified in the right-hand side of the policy, an indication of the policy (access *allowed* or *denied*), an indication of whether the policy is pre-defined and cannot be deleted, and an indication of whether the policy is presently active. The difference between the classes is what can be on the right-hand side of the policy, and therefore the links to the entities on the right-hand side; in the case of access policies and policy maker policies the right-hand entities are information sets only, and consequently, tables of the *Policies Access* and *Policies Policy Maker* classes contain right-hand links only to tables of the *Resource Groups* class, while tables of the *Policies Administer* class may contain right-hand links to in the alternative tables of class *User Groups*, tables of class *Resource Groups*, tables of class *Sites*, tables of class *Servers*, tables of class *Services*, and tables of class *Resources*.

The rights given the user group specified by the user group on the left-hand side of an administrative policy over the sets of entities specified by the right-hand side vary depending on the kind of entity, as shown in the following table:

Left-hand Side	**Right-hand Side**	**Meaning of "allowed" Access**
User group	any	Members of the user group can create administrative policies for the target or included items. This allows for the delegation of responsibilities.
User group	User group	Members of the user group can administer the target user group, including nested user groups. Allowed administration includes deleting, moving, and copying the target user group; nesting it in another user group; adding members to it; and nesting other user groups in it.
User group	Information set	Members of the user group can administer the information set, including nested information sets. Allowed administration includes deleting, moving, and copying the target information set; nesting it in another information set; adding members to it; and nesting other information sets in it.

User group	Site	Members of the user group can administer the site, including elements under it from the Available Resources list (all Access Filters, servers, services, and resources). Allowed administration includes deleting and moving the site; adding it to an information set; and adding locations and Access Filters to it. Control over the Intranet location is necessary in order to define new Access Filters.
User group	Access Filter	Members of the user group can administer the Access Filter, including elements under it from the Available Resources list (all servers, services and resources). Allowed administration includes deleting and moving the access filter; adding it to an information set; and adding servers or services to it.
User group	Server	Members of the user group can administer the server, including elements under it from the Available Resources list (all services and resources). Allowed administration includes deleting and moving the server; adding it to an information set; and adding servers or services to it.
User group	Service	Members of the user group can administer the service, including resources under it from the Available Resources list (all resources). Allowed administration includes deleting, moving, and copying the server; adding it to an information set; adding resources to it.
User group	Resource	Members of the user group can administer the resource. Allowed administration includes deleting, moving and copying the resource and adding it to an information set.

The following table describes the rights given administrative user groups when they appear on the left-hand side of a policy maker policy:

Left-hand Side	**Right-hand Side**	**Meaning of "allowed" Access**
User group	Information set	Members of the user group can manage access policies controlling access by any user group to the information set, including nested information sets. They may also include the information set and any of its descendants in a further policy maker policy.

As pointed out in the discussion of the Information Set tables above, the proxy that is doing the access checking can use the User Group tables and the Information Sets tables to find the user groups the user making the access request belongs to and the information sets the information resource being accessed belongs to and can also use these tables to determine the trust level of the user identification and the sensitivity level of the information resource. The proxy can thereupon use the Policies Access tables to find whether any of the user groups the user belongs to may access any of the information sets

the information resource belongs to. If any such user group is found, the user may access the information set if the request's trust level is as high as the information resource's sensitivity level. To determine the request's trust level, the proxy must determine the trust level of any encryption technique being used and/or the trust level of the path in VPN 201 that is being used for the access. This information is available in access filters tables 1701, shown in FIG. 17 and described below. If either the access policies or the access request's sensitivity level do not permit the access, the message is disregarded and any session it belongs to is dropped. The access checking process is substantially the same when the request is a request by a user who is a member of an administrative user group to access database 301, except that when access is permitted, it may result in a modification of the database in accordance with the rules set forth above. That modification will then be propagated to all other access filters 203 in VPN 201.

Server Tables: FIG. 17

FIG. 17 shows the schema for tables that are particularly significant for the operation of servers in the VPN. There are three kinds of servers in the VPN:

- Plain servers. These are the servers upon which the resources are stored and which execute the services by means of which the resources are accessed.
- Access filters 203.
- Policy manager servers. These are access filters 203 that additionally coordinate and distribute database 301 and/or generate reports about operation and status of the VPN.

An access filter 203 may function additionally as a plain server.

There is a table of class *Servers* 1417 for every server in the VPN. Information in the table for each server included its ID, name, domain in the Windows NT brand operating system, its Internet name, whether it is an access filter 203 and additionally a policy server, whether access to it is available only via an access filter 203, and whether it is inside the VPN. If the server is an access filter 203, it additionally has an identity that access filter 203 provides to other entities in VPN 201 for purposes of authentication and encryption. In a preferred embodiment, the identity is the X.509 certificate for the access filter used by

SKIP. The X.509 certificate also includes a public key for access filter 203. The public key may belong to one of a number of name spaces; the NSID (name space ID) is an identifier for the public key's name space; the MKID (master key ID) identifies the public key within the name space. Also included in the table is a link to a table of class *Certificate Authority* 1711 that indicates the certificate authority that issued the X.509 certificate for the access filter. Of course, servers other than access filters may also have X.509 certificates, and in that case, their *Server* tables will have the server's NSID and MKID.

Every plain server in the VPN has one or more services running on it. For example, an FTP service provides access to files (the resources) on the server according to the file transfer protocol of the TCP/IP protocol suite. Each table of class *Servers* 1417 for plain servers has links to a group of tables that define the services and resources available on the server. As shown at 1719, these tables include tables of class *Services 1413*, which represent the services, tables of class *Resources* 1409, which represent the resources available via the services, and tables of class *Service Definitions* 1715 which define the service.

The remainder of the tables for which FIG. 17 gives the schemas contain information that is used by access filters 203. The tables whose classes are shown at 1705 contain information used by access filters 203 that are policy managers to distribute database 301 and/or to generate reports; the tables whose classes are shown at 1717 contain information about optional parameters for the software being run by a given access filter 203; those whose classes are shown at 1709 contain information about the proxies and other software modules that access filters 203 use to do protocol-level access checking in access filter 203; and the tables at 1707 contain information about trust and sensitivity definitions for identifications of users and kinds of encryption.

The tables indicated by the reference number 1708 contain information about the VPN to which access filter 203 belongs. Access filter 203 uses this information to route sessions and also to determine the trust level of the path being used for a given session. *Routing table* class 1721 defines tables that list the current routes to all networks accessible from

access filter 203. It is automatically updated as those routes change. *Attached Network* class 1723 defines tables that indicate for each access filter 203 the networks that access filter 203 is presently attached to; tables of that class contain links to tables of class *Network Definition*, which in turn contain a link to a definition in trust definitions 1707 which indicates the trust level of the network. The last class in this group is *Point to Point Connection* 1713, which defines tables that describe connections between access filters 203 accessible via the VPN. There is a table for each combination of source and destination access filter 203 and a link to a trust definition that specifies the trust level of the path between the source and destination access filters 203. The trust level in this table is based on the encryption technique used for messages traversing the path.

As previously explained, the User Group tables 1301 and the Information Sets tables 1401 provide the information needed by access filter 203 to determine whether the access policies of tables 1601 permit the access and also provide information about the sensitivity level of the resource being accessed. Access filters tables 1701 additionally provide the information needed by access filter 203 to determine the minimum trust level of the path in the VPN being taken by the session and the trust levels of the available encryption algorithms. Thus, if access filter 203 determines that a given user wishing to access a given resource belongs to a user group which has the right to access the information set to which the given resource belongs and that the authentication level used for the user's identification is no lower than that required for the resource's sensitivity level, access filter 203 can further determine whether the trust level of the path is sufficiently high, and if it is not, access filter 203 can raise the trust level the necessary amount by selecting an encryption algorithm with the required trust level and encrypting the session.

Available Information Tables: FIG. 15

Fig. 15 shows the schema for available information tables 1501. The tables are used by filter 203 to produce available resources display 1005, shown in FIG. 10. The table classes shown at 1502 relate each server to its services and to the resources provided by the services. The table classes shown at 1504 organizes the available resources into a hierarchy for inheritance purposes and are also used to produce the hierarchical list shown at 1005,

and by following the links from the *Site Elements* tables to the *Servers* tables, access filter 203 can determine the hierarchy of sites, servers, services, and resources. The table classes at 1503, finally, establish a distribution tree of access filters 203. As will be explained in more detail later, when access control database 301 is modified, the tree defined by those tables determines the order in which modifications are distributed to the access filters.

Modifying Access Control Database 301: FIG. 19

As previously mentioned, each access filter 203 has an exact duplicate of the copy of access control database 301 belonging to master policy manager 205 in access filter 203(a) of FIG. 2. FIG. 19 shows how that copy of access control database 301 is modified and how the modifications are distributed from access filter 203(a) to the other access filters 203.

FIG. 19 shows access filter 203(a) with master policy manager 205 and another access filter 203(i) at which an administrator using a workstation is modifying access control database 301. The messages 1909 needed to distribute and synchronize the modifications are encrypted using SKIP and sent via VPN 201 using a protocol called the private communications service (PCS). Each of the access filters has a number of copies of access control database 301. Any access filter 203 has at a minimum two copies: live database (LDB) 1907, which is the database currently being used to do access checking, and mirror database (MDB) 1905, which is a copy of the database that can be switched in to be used in place of live database 1907. Thus, access filter 203(a) has an MDB 1905(a) and an LDB 1907(a) and access filter 203(i) has MDB 1905(i) and LDB 1907(i).

If an access filter 203 is being used by an administrator to modify access control database 301, then it will additionally have at least one working database (WDB) 1903. The working database is a copy of the database that is not being used to control access and therefore can be modified by the administrator. The administrator does so using a workstation or PC connected via a network to the access filter. The workstation or PC displays the administrative graphical user interface described above, and the administrator uses the GUI to make the changes as enabled by administrative policies. The changes may

affect any aspect of the information stored in access control database 301. As indicated above, where the changes are changes in access or administrative policies, the administrator can use the policy evaluation feature to see the effect of the changes. When the administrator is satisfied with the changes, he or she clicks on the apply button and the changes are distributed to all of the access filters and incorporated into each access filter's live database.

The process of updating all of the live databases is called database synchronization and distribution. The process has three phases:

- First, the modifications are sent from the access filter 203 where they were made (here, access filter 203(i)) to access filter 203 to which the master database belongs (here, access filter 203(a)).
- There, the changes are incorporated into the master database. This is done by incorporating the changes into mirror database 1905(a), then swapping live database 1907(a) and mirror database 1905(a), and then changing the new mirror database 1905(a).
- Then, the changes are distributed from the Master Policy Manager to other Access Filters.

At each access filter 203, synchronization is done in the same fashion as with access filter 203(a). The order in which the changes are made in the access filters 203 of VPN 201 is determined by distribution tree 1511, which in turn is set up using filters display 1201. The access filter 203 with master policy manager 205 is always the root of the tree. By default, the first access filter 203 installed in VPN 201 has master policy manager 205. As other access filters 203 are installed, they are added to the tree as children of the Master Policy Manager.

The Master Policy Manager distributes changes to its children sequentially. As each child access filter 203 receives its distribution, it then distributes to its children. This means that a shallow distribution tree with many branches off the top level will complete a distribution cycle faster than a deep distribution tree with few branches off the top level. An administrator with the proper access can reconfigure the distribution tree to make

distribution more efficient.

If two administrators have modified the same piece of information (for example, an access filter definition) in different working data base 1903, a synchronization conflict can occur. When this happens, master policy manager 205 decides which modification to incorporate into access control database 301.

Optimizing Access Control Database 301: FIGs. 21 and 23

Although appropriate for persistent storage and use by administration GUI 1915, database 301 is not optimized for use in real-time access checking. As will be explained in more detail below, access filter 203 optimizes the data in database 301 that is required for run-time access checking and to make the display for the IntraMap. It does the optimization each time a new copy of database 301 is received in access filter 203. In its optimized form, database 301 is a set of Memory Mapped Files (MMFs) in which the access policy information is stored in a form which permits quick access. The MMFs are so called because they are generated as normal files, but then attached to a program's memory space and accessed by means of memory operations instead of file operations. A further optimization is achieved by using the MMF files to generate rules that are used to do low-level filtering of messages by IP source and destination addresses and port numbers for which access is allowed or denied.

FIG. 21 shows an example MMF file 2303. The MMF file in question is *DBCertificatesbyUserGroupFile* 2101, which maps the certificate matching criteria used to identify certificates that belong to particular user groups to identifiers in database 301 of records for the user groups specified by the certificate matching criteria. File 2101 thus permits a proxy that has the certificate that identifies the source of a message that has been encrypted using SKIP to quickly determine the user groups that the user identified by the certificate belongs to. In the preferred embodiment, the certificate matching criteria are the O, OU, and CA fields of the X.509 certificate.

All MMF files 2303 have the same general form: there are two main parts: a header 2103

which contains the information being mapped *from* and a data part 2105 which contains the information being mapped *to*. Header 2103 contains a list of entries 2107. Each entry contains a value being mapped from (in this case certificate matching criteria (CMC) 2109) and a pointer 2111 to a record in data 2105 which contains the information being mapped to (in this case, a list 2115 of identifiers 2113 in database 301 for the user groups that the user identified by CMC 2109 belongs to). The entries in header 2103 are sorted by the information being mapped from (here, CMC 2109), so that standard fast searching algorithms can be used to locate an entry 2107 corresponding to a given set of certificate matching criteria.

FIGs. 23 A, B, and C provide a complete list of the MMF files 2301 that are employed in one implementation of access filter 203. The relationship between these files and the tables of database 301 will be apparent from the descriptions of the contents of the files provided in the table. Each MMF file 2303 is represented by an entry in the table which indicates the file's name and its contents. The files are subdivided into groups 2311, 2313, 2319, 2321, 2323, and 2422. Files of particular interest are DBUsersFile 2307 and DBResourcesFile 2309, which describe policies, DBCertificatesByUserGroupFile 2101, which is the MMF file shown in detail in FIG. 21, DBResourceIDbyServiceIDFile 2315, which relates URLs of resources to resource IDS, DBResourcesbyResourceIDFile 2317, which relates resources to resource groups, and DBTrustTableFile 2325, which implements SEND table 601. Moreover, the
following files are used to compile rules:

DBServerIDByNameFile
DBIPAndTypeByServerIDFile
DBServicePortToProxyPortFile
DBAttachedNetworksByServerIDFile
DBRoutingTableFile
DBRoutingTablebyServerIDFile

The files in IntraMap information 2422, finally, are filtered to make list 2431, which is then downloaded to the client for use by IntraMap applet 2411.

Details of Access Filter 203: FIG. 20

FIG. 20 is a block diagram of the architecture 2001 of an access filter 203. In the implementation shown in FIG. 20, all of the components of access filter 203 other than NIC cards 2013 are implemented in software. The software of the implementation runs under the Windows NT brand operating system manufactured by Microsoft Corporation. The software components fall into two broad classes: those that run as applications programs at user level 2003 of the operating system and those that run at the kernel level 2005 of the operating system. In general, the programs that run at the kernel level do IP-level access checking and encryption and authentication, while those that run at the user level do application- level access checking. Also included in the user-level components are software that manages access control database 301 and software that produces the MMFs and rules for IP-level access checking from access control database 301. The following discussion will begin with the kernel components, continue with the user-level components related to access control database 301, and will then deal with the components for protocol-level access checking.

Kernel-Level Components

Network Interface Cards (NICs) 2013: These are the ethernet and token ring cards installed in access filter 203. Three network cards are typically configured. One is configured for the interface to the Internet, to a wide area network (WAN) 2011, or to a network connected to another access filter 203. Another is configured for interface 2007 to all client computers and a third is configured for interface 2009 to the servers providing TCP/IP services. If there is no need for an access filter 203 to be interposed between clients and servers, there may be only two NICs 2013, one to WAN 2011 and the other to a LAN. There will be no need for the access filter to be interposed if no servers exist at access filter 203's location or if it is acceptable for all local clients to have access to all local information resources.

SHIM 2017: at installation time, a shim software module is inserted between two levels of the Windows NT brand operating system (the NDIS and TDIS levels). This causes all

traffic for particular protocols to pass through SHIM 2017. In the implementation, all traffic for TCP/IP protocols pass through SHIM 2017, while non-TCP/IP protocol traffic goes directly from the NIC to the appropriate other kernel modules. SHIM 2017 invokes SKIP module 2021 as required to process the TCP/IP protocol traffic.

SKIP module 2021: All IP network traffic is sent through SKIP module 2021. If an incoming packet is not SKIP type, i.e., does not require the authentication and decryption services performed by SKIP, then SKIP module 2021 passes it to IP filter module 2019. Similarly, if an outgoing packet is not to be encrypted, then SKIP module 2021 sends it directly to the proper NIC 2013 for transmission. With SKIP-type packets, authenticator 2024 in SKIP module 2021 serves to authenticate a session and encryptor/decryptor 2022 serves to encrypt and decrypt information at a session level. Both authentication and encryption/decryption may be done with an arbitrary number of other access filters 203, servers that employ SKIP, and clients that employ SKIP. Authentication and encryption algorithms are set by IP filter module 2019 for outgoing packets based on SEND parameters or are specified within incoming packets.

SKIP module 2021 maintains enough state information for each other site that it talks to so that it can maintain high-speed operation for most SKIP-type packets. Packets are sometimes 'parked' while additional processing (shared secret and temporary key calculation) is performed. 'skipd' module 2037 in user space 2003 performs this extra processing.

IP Filter 2019: The IP filter operates on a set of rules that the rules compiler, a component of database service 2029, makes from the access policies in access control database 301. The basic functions of IP filter 2019 are to:

a. Pass traffic up to the TCP/IP stack.

b. Block traffic – explicitly drop traffic for specific IP addresses and according to special rules for emergency conditions.

c. Drop traffic – implicitly drop traffic that neither matches any rules nor is allowed by any policies.

d. Proxy traffic – rather than deliver traffic to the indicated destination, route it to a proxy application on the current machine.

e. Perform network address translation – change potentially illegal internal IP addresses to legal ones.

f. Pass decisions off to pr_ipf (discussed below) upon establishing a new session for which access control cannot be decided strictly by the rules. Typically, this is for sessions that may be allowed by policies or by the VPN tunneling features described previously.

IP filter 2019 performs these functions based on the following information:

- Rules generated by the rule compiler;
- Source and destination IP address and port;
- Encryption, or lack of it, on the incoming packet; and
- Desired encryption and authentication on outgoing packets.

Components having to do with Database 301

Shared Directory 2028: VPN 201 uses a single access control database 301 that is kept resident in each and every access filter 203. All versions of database 301 in a given access filter 203 are maintained in shared directory 2028. Shared directory 2028 also contains each access filter 203's log files.

Private Connect Service (PCS) Module 2025: PCS module 2025 provides access filter- to-access filter communications in VPN 201. All such communications go through the PCS. The PCS has its own IP port number and its messages must be encrypted. The particular functions carried out by means of PCS messages are:

- Distribution tree management;
- Distribution and synchronization of database 301;
- Retrieval and distribution of routing table 1721;
- Retrieval of Windows domain and user information;
- Network scanning;
- Retrieval of log contents; and

- Transfer of files used by reporting and other subsystems.

ISDB Manager 2027: ISDB manager 207 manages database 301. It and the PCS are the only interfaces to the copies of database 301 in each access filter 203. It contains the software used to read and write all tables in the copies of database 301.

DB Service and Rules Compiler 2029: DB Service 2029 produces MMF files 2301. It does so each time a new copy of database 301 is received in access filter 203. It utilizes the functions provided by ISDB Manager 2027 to read live database 1907(I) for a given access filter 203(I) and generate the MMFs 2301. A component of DB service 2029 is the Rule Compiler, which generates rules for use in the IP filter module from relevant ones of the MMFs 2301. The rules specify IP sources, destinations, and port numbers for which access is allowed or denied. The Rule Compiler exists as both a DLL and an application program that simply invokes routines in the DLL. In normal operation, the routines in the DLL are invoked by the DB Service whenever a modified database 301 is received in access filter 203(I) from master policy manager 205. The application program is used in special modes during the installation and bootstrapping process.

Memory Mapped Files (MMFs)2301: As already explained, the MMFs 2301 are data files generated by DB Service module 2029 and utilized by a number of other modules in access filter 203. The files are designed to make the following operations as efficient as possible:

- Map from user identification to user group(s);
- Map from information resource to information set(s);
- Find policies that are associated with user groups; and
- Find policies that are associated with information sets.

Components related to Authentication

Evaluator 2036: Evaluator 2036 is a set of DLLs that are used by each proxy in proxies

2031. Evaluator 2036 provides the following functions to the proxies:

- Prompting the user for further in-band or out-of-band identification information;
- Obtaining out-of-band authentication information from the Authentication Tool Service (ATS);.
- Obtaining the certificate associated with the current user from SKIPd;
- Reading the MMFs 2301 and determining whether the access policies permit the user to access the resource; and
- Implementing the trust/sensitivity calculations for the path if access is otherwise allowed, including deciding whether access may be allowed via the path and if so, what encryption and authentication is needed and which access filter is nearest the server. These functions are performed by a component of evaluator 2036 termed the VPN manager.

Authentication Tool Service / User Identification Client (ATS/UIC) 2039 and 2041: ATS 2039 is the server in a client-server application that gathers and authenticates user information. ATS 2039 runs on the computer upon which the other components of access filter 203 are running. The client part is UIC 2041, which runs on Windows-based clients. ATS 2039 and UIC 2041 are the mechanism by means of which access filter 203 obtains out-of-band authentication information. ATS 2039 and UIC 2041 communicate by means of a session which is separate from the session being authenticated. ATS 2039 gathers and caches the authentication information it obtains from the UIC clients and provides it to Evaluator 2046. The cached information from the clients includes

- Windows ID;
- Identity Certificates; and
- Authentication token ID's.

SKIPd 2037:

Most of SKIPd's functions are in support of SKIP 2021. Those functions include:

- Exchange of certificate information with other communications partners. This is done through the use of the Certificate Discovery Protocol (CDP).
- Calculation of the Diffie-Hellman shared secret. This shared secret is key to the

operation of SKIP. This calculation can take a considerable amount of time and is saved to disk in an encrypted form.

- Calculation of the transport key used to encrypt the session. These keys last for a period of time or amount of data.
- In addition, SKIPd will provide certificate matching criteria to the Evaluator(s) for use in user identification.

Proxies 2031

As previously explained, a proxy is software in filter 203 that intercepts traffic for a particular protocol. The proxy 'understands' the protocol that it is intercepting and can obtain the information required to identify the resources being accessed and/or to authenticate the user from the messages that are being exchanged during the session. All of the proxies but SMTP receive messages on ports other than the standard ports for their protocol, with the IP filter redirecting messages using a given protocol from its standard port to its non-standard port. The proxy provides the information it has obtained from the session to evaluator 2036 to decide whether the user has access to the information resource. If the user does have access, access filter 203 forwards the incoming messages to the server to which they are addressed and the messages are processed further in the server by the service for the protocol. In the following, each of the protocols employed in a preferred embodiment is discussed; of course, other embodiments may include proxies for other protocols.

Pr_ipf: The majority of network traffic occurs over a small number of protocols for which there are proxies in access filter 203. However, even where there is no proxy, an access decision must be made. In some cases, the decision can be made at the kernel level by IP filter 2019; when it cannot be, IP filter 2019 provides the traffic to pr_ipf, which obtains whatever information relative to user identification and information resources it can from the traffic and passes the information to evaluator 2036 to determine whether access should be granted. Pr_ipf is not truly a proxy, since it only makes an access determination for IP filter 2019 and does not pass any traffic to standard protocol software.

FTP: The FTP proxy handles TCP/IP packets for the File Transfer Protocol. In a present embodiment of VPN 201, access control is only enforced to the account (logon) level; in other embodiments, access may be controlled to the file access level. During the FTP logon portion of the protocol, the proxy determines the server and account being accessed and provides this information to evaluator 2036 to determine whether the user belongs to a user group whose members may access the information sets corresponding to the account. The proxy further handles the in-band authentication using tokens in interactions with the user that are specified in the FTP protocol.

FTP is actually a very complex protocol, involving both an active and passive mode (used in Web browsers and some automated FTP clients). In addition, FTP data transfers utilize a second, dynamically determined TCP session. This requires a special interface between the FTP proxy and IP Filter 2019 so that the FTP proxy can indicate to IP filter 2019 that it should allow the second session.

HTTP: The HTTP proxy is built from the source code for the public domain CERN implementation of HTTP and contains all of its caching logic. The proxy uses evaluator 2036 to check each access to a URL. No in-band authentications are performed with HTTP.

Telnet: The Telnet resource is only controlled to the server level due to the non-standardized nature of Telnet logins. The Telnet proxy is only used in order to provide additional in-band authentications. It is the simplest of the true proxies.

NNTP: The NNTP (Network News Transfer Protocol) is used to control both news feed and news reading operations. During the feed operation, the NNTP proxy watches for uuencoded messages. These are binary messages that have been translated into ASCII text for the purposes of transmission. Such messages are often broken up into multi-part messages to keep them to a reasonable size. The NNTP proxy caches all parts of binary messages. For each such message, if that message is the last part that will complete a multi-part message, then the entire multi-part message is assembled and anti-virus 2033

checks it for viruses as described in more detail below. During the news reading operation, access is protected to the news group level. As in other proxies, evaluator 2036 is used to determine if the current user may access the news group.

Real Audio: The Real Audio proxy allows clients to access real audio servers that are protected at the server level only. The real audio protocol utilizes a standard TCP socket connection to establish a session, but then uses a return UP channel. As with FTP, the real audio proxy has an interface to IP filter 2019 that permits it to indicate to IP filter 2019 that the return UP channel is allowed.

SMTP: The SMTP (Simple Mail Transfer Protocol) differs from the other proxies in that the IP Filter's proxy rules are not used to redirect traffic to the SMTP proxy. Whereas the other proxies 'listen' on a non-standard port, the SMTP proxy listens on the standard port (25) and then makes its own connections to the standard SMTP server software. The access policies in database 301 must explicitly allow this access.

IntraMap: When a user specifies the URL for the IntraMap, report manager 209 downloads the IntraMap Java applet and the downloaded applet attempts to make a connection back to a socket of the access filter 203 that has report manager 209. IP filter 2019 of local access filter 203(I) intercepts the attempt to make the connection and provides it to the IntraMap proxy on local access filter 103(I) The proxy responds to queries from the applet by finding the answers in the local copy of database 301 and returning the answers to the applet, with all answers being filtered to reflect the user's access rights. The IntraMap proxy is not a true proxy in that the entire connection is always completely serviced by the instance of the IntraMap proxy that intercepts the connection.

Anti-Virus Module 2033

Anti-virus module 2033 in a preferred embodiment is a set of DLLs provided by Trend Micro Devices, Inc., Cupertino, CA. In other embodiments, anti-virus modules from other sources may be used. Anti-Virus module 2033 checks all data entering VPN 201

for viruses. In order to provide the user with feedback on the progress of the transfer and to prevent the user's client program from timing out, the data is transferred to the client and is copied at the same time into a temporary file used for virus checking. The last portion of the data, however, is not sent to the client until after virus checking is complete. As soon as the last portion is in the temporary file, the temporary file is checked for viruses. If no viruses are detected, the remainder of the data is sent to the client. If a virus is found, then the transfer is aborted. In a present embodiment, the user is notified of a failed transmission. If an administrator has so specified, an alert may be sent to the administrator.

Launch, Log, Alert and Reports 2027

The components of this module perform the following functions:

- Launch – controls the initial sequence of startup tasks that takes place on an access filter 203 when VPN 201 is established.
- Logs – a DLL that provides a standardized logging interface.
- Alerts – a standalone program that watches all of the NT logs, looking for alert conditions specified in database 301. The method by which an alert is delivered is specified using the GUI for defining alerts.
- Reports – a subset of the logs are forwarded to a special report log, concentrated into a database and later forwarded to Report Manager 209.

Administrative Graphical User Interface 1915

The GUI may run on access filter 203 or on any computer having a 32-bit Windows brand operating system that is attached to access filter 203. Whether the GUI runs on access filter 203 or on an attached system, it utilizes ISDB MANAGER 2027 to read from and write to a working copy 1903 of access control database 301. All necessary modifications to access control database 301 are made through GUI 1915. An 'apply' operation in the GUI is sent as a signal to PCS 2025, which responds to the signal by starting the previously-described distribution and synchronization operation.

Detailed Example of Operation of Access Filter 203: FIGS. 5 and 22

In the following, the end-to-end encryption example of FIG. 5 will be explained in detail. In that example, a roamer 503 whose PC is equipped with SKIP is accessing a SKIP-equipped server 407 inside a site on VPN 201. When roamer 503 was set up to access VPN 201, it was set up to do so via access filter 403(3) using a particular type of encryption. Here, it will be assumed that the type of encryption being used by roamer 503 has a trust level of "secret" and that the user wishes to access a Web page on server 407 that has a sensitivity level of "secret". Since what is being accessed is a Web page, roamer 503 is using the HTTP protocol for its session with the HTTP service on server 407. Since roamer 503, the access filters 203 in VPN 201, and server 407 are all equipped with SKIP, they are all provided with their own public and private keys. At a minimum, roamer 503 also has the certificate and public key for access filter 403(3) to which it directs messages for servers internal to VPN 201; access filter 403(3) has the certificate and public key for roamer 403 (or obtains them using the Certificate Discovery Protocol); all access filters 203 in VPN 201 have or can get each others' public keys and the public keys for servers in VPN 201 that are equipped with SKIP. Additionally, each access filters 203 in VPN 201 knows the IP addresses of all of the other access filters 203 and servers in VPN 201.

All of the messages which are sent and received as part of the HTTP session between roamer 503 and server 407 are encrypted and authenticated by SKIP. FIG. 22 shows the form taken by such a SKIP message 2201. The SKIP message is made by SKIP software on the system which is the source of the SKIP message. SKIP message 2201 shown here is from roamer 503. Its main components are:

Outer IP header 2203: Outer IP header 2203 is used to deliver the SKIP message to access filter 403(3). Contained in outer IP header 2203 are a source IP address 2209 for roamer 503 and a destination IP address 2206 for access filter 403(3). Destination address 2206 used by roamer 503 was set to specify access filter 403(3) when roamer 503 was set up to access VPN 201. Source IP address 2209 may be dynamically assigned to roamer 503 by the Internet service provider that roamer 503 uses to connect

to Internet 121. Outer IP header 2203 further contains a message type (MT) field 2208 which specifies that the message is a SKIP message.

SKIP header 2205: SKIP header 2205 contains the information needed to decrypt SKIP message 2201 when it is received. SKIP header 2205 contains at least a destination NSID 2215 and destination MKID 2213 for the destination's certificate, that is, the certificate for access filter 403(3), and the source NSID 2219 and source MKID 2217 for the source's certificate, that is, the certificate for roamer 503. In addition, SKIP header 2205 contains identifiers for the algorithm used to authenticate the message (MAC ALG 2226) and the algorithm used to encrypt the message (CRYPT ALG 2225), as well as an encrypted transport key for decrypting the message (Kp 2223) and an identifier 2224 for the algorithm used to decrypt the transport key.

Authentication header 2211: Authentication header 2211 contains a MAC (message authentication code) 2221, which is computed according to the MAC algorithm identified in field 2226 and which is used by access filter 403(3) to verify that the message arrived without tampering.

Encrypted payload 2227: Encrypted payload 2227 contains the encrypted message which roamer 503 is sending to server 407, including IP header 2331 for that message and encrypted message 2229. IP header 2331 has the IP address for server 407 and the port number for the HTTP protocol service. Encrypted payload 2227 can be decrypted by using Kp 2223 with the decryption algorithm specified by CRYPT ALG 2225.

Handling SKIP Message 2201

SKIP message 2201 arrives on Internet interface 2011 of access filter 403(3). Processing of the message begins at the SHIM level in kernel 2005. SHIM 2017 sends all incoming traffic to SKIP 2021, which in turn recognizes from MT field 2208 that the message is a SKIP message. To decrypt and authenticate the message, SKIP needs to decrypt Kp , and to do that it provides SNSID 2219, SMKID 2217, DNSID 2215, and DMKID 2213 to SKIPd 2037, which uses the IDs to retrieve the certificates for roamer

503 and access filter 403(3) from SKIPd 2037's certificate cache. If a certificate is not there, SKIPd 2037 uses the CDP protocol to fetch the certificate. The information in the certificates is then used together with access filter 403(3)'s private key to create a shared secret value, which is then used to decrypt transport key Kp 2223 and to produce two internal keys, Akp and Ekp. SKIP securely saves the shared secret for use with future messages, since its computation takes a significant amount of time. Next, a MAC is computed for the entire received message and the Akp is used with MAC 2221 and MAC ALG 2226 to verify that entire message 2201 has not been tampered with. If that is the case, the key Ekp is used to decrypt encrypted payload 2227 to recover the original message from roamer 503. Decrypted payload 227 is then provided to IP filter 2019, which applies its rules to the source IP address, destination IP address, and port number of IP header 2231. If no rule denies access, IP filter 2019 follows another rule and redirects the unencrypted message together with SNSID 2219 and SMKID 2217 to the port for the HTTP proxy. IP filter 2019 uses the DBServicePortToProxyPortFile of MMFs 2301 to find the port in question.

Processing continues at the application level in user level 2003 of the operating system. The HTTP proxy has in hand the IP address of the server, the port number of the service, the URL for the Web page, the certificate belonging to the user of roamer 503, and the encryption method used to encrypt the message. It will use evaluator 2036 to determine the following from the MMF files 2301:

- the user groups that the user represented by the certificate belongs to;
- the information sets that the Web page belongs to;
- whether there is an access policy that permits at least one of the user groups to access at least one of the information sets; and
- whether the trust level of the message is at least equal to the sensitivity level of the Web page.

Beginning with the first of these tasks, evaluator 2036 receives the NSID and MKID for the certificate and uses the certificate matching criteria from the certificate with the DBCertificatesByUserGroupFile to obtain the identifiers for the user groups the user sending the message belongs to.

Evaluator 2036 determines the information sets by taking the IP address of the server, the port number of the service, and the URL for the Web page and using the IP address with the DBServerIDByIPFile to determine the server that contains the Web page, the port number with the DBServiceIDByPortFile to determine the service on the server that provides it, and the URL with the DBResourceIDbyNameFile to get the identifier for the resource in database 301, and then uses the DBResourcesByResourceIDFile to get the identifiers for the information sets that the Web page belongs to.

With the identifiers in database 301 for the user groups and information sets in hand, evaluator 2036 uses the DBResourcesFile to determine whether there is an access policy which permits any of the user groups that the user belongs to access any of the information sets that the Web page belongs to. In so doing, it may only consider user groups whose membership is determined using modes of identification whose trust levels are sufficient for the resource's sensitivity level. The DBResourcesFile maps each information set identifier to a list of the user groups for which there are access policies involving that resource set. For each user group, the DBResourcesFile further indicates whether the policy allows or denies access. Evaluator 2036 uses the DBResourcesFile to determine for each information set in turn that the Web page belongs to whether the list of user groups for which there are access policies with regard to the information set includes one of the user groups to which the user belongs. If there is an access policy for any of the user groups that denies access, the evaluator indicates to the HTTP proxy that access is denied; if there is no access policy for any of the user groups that denies access and at least one that allows access, the evaluator indicates to the proxy that access is allowed; if there is no access policy of any kind for any of the user groups, the evaluator determines if there is at least one certificate or token based user group that has an allow policy for the resource. If so, and the requesting client has a UIC running, then the UIC is contacted to ask the user for additional identity information; if additional identity information comes back, the process described above is repeated. Otherwise, the evaluator indicates to the HTTP proxy that access is denied.

Of course, evaluator 2036 will also deny access if the access request does not have a

trust level equal to the sensitivity level of the Web page. Evaluator 2036 obtains the sensitivity level of the Web page from the DBResourcesByResourceIDFile, the trust level of the user identification from DBTrustAuthenticationsFile, and the trust level of the encryption method from the DBTrustEncryptionsFile. Since SKIP has encrypted the message with a method that has the "secret" trust level, the trust level of the path through the network is not of concern in this example. To determine whether the trust levels for the user identification and the encryption method are sufficient for the sensitivity level of the Web page, Evaluator 2023 uses the DBTrustTableFile, which effectively implements SEND table 601. If the trust levels are sufficient, Evaluator 2036 indicates to the proxy that the access is allowed.

Once the proxy has confirmed that access is to be allowed to the information resource specified in the message, the proxy originates a new session to the actual service, the HTTP service on server 407. Proxy 2031 sends a special message to IP filter 2019 telling it to allow the specific session through, since otherwise this session would probably be blocked by rules or sent again to a proxy. The message to IP filter 2019 also includes information about the encryption needed for the new session, which in this example is that the session should be encrypted to the final access filter 403(5) and should use encryption suitable for the data sensitivity level, which is secret. When IP filter 2019 encounters the new session, it finds that it matches the criteria specified by proxy 2031, so it passes the session to SKIP. Since encryption is needed for this session, the message will be reencrypted. SKIP 2021 creates a SKIP message 2201 in the same fashion as described above, except that:

- Outer IP header 2203 for the message specifies access filter 403(3) as the source of the message and access filter 403(5) as the destination;
- SKIP header 2205 has SNSID 2219 and SMKID 2217 for access filter 403(3) and DNSID 2215 and DMKID 2213 for access filter 403(5), and the other values in header 2205 are also those required by the fact that the source and destination for the message are now access filter 403(3) and access filter 403(5);
- Encrypted payload 227 is the same as before (except that it has been encrypted using a different key) and MAC 2221 is produced as required for entire new

message 2201.

As the proxy is relaying the message it is also watching for file transfer types that might contain viruses. When it encounters one, it applies anti-virus software 2033 to these files. If a file contains a virus, the proxy fails to deliver the complete file, thereby rendering the virus harmless. If access control database 301 so indicates, the proxy sends an alert when anti-virus software 2033 detects a virus.

As new SKIP message 2201 is received at access filter 403(5), it is passed to SKIP 2021, where it is authenticated and decrypted as described previously. By the same mechanism as described above with regard to access filter 403(3), IP filter 2019 on access filter 403(5) recognizes that the message is destined for the HTTP application protocol, so it directs it to HTTP proxy 2031. That proxy accepts the message, then sends information it can obtain about the message's originator (access filter 403(3) from outer IP header 2203 and SKIP header 2205 to evaluator 2036 to determine whether the session being instigated by this message should be allowed to proceed. Evaluator 2036 examines the source IP address of the message as well as the other identity information, and by looking up the source IP address in the MMF file DBServerIDByIPFile, determines the identifier in data base 301 for access filter 403(3), uses that identifier to locate access filter 403(3)'s certificate, and finds that certificate information matches the retrieved certificate associated with access filter 403(3)'s message being processed. The source of the message, access filter 403(3), is thereby recognized as an access filter 403 within VPN 201, so evaluator 2036 responds that the session should be allowed, for the reason that it is a message already permitted by another access filter 403 within the same VPN 201. This decision to allow the message is returned to the http proxy 2031. The evaluator 2036 will instruct http proxy 2031 on access filter 403(5) to allow any request that comes over the same session, for the same reason. As the http request is processed, the proxy will establish an outgoing connection to the http service on server 407, in the same manner as the outgoing session was established on access filter 403(3).

When the connection is initiated to server 407, evaluator 2036 looks up the IP address of server 407 in the MMF file DBServerIDByIPFile to determine the identifier in

database 301 for server 407, uses the identifier to locate the table for the server, and uses the certificate identifier from that table and the DBCertificatesFile to find the certificate for server 407. Then it uses the keys for access filter 403(3) and the public key for server 407 (obtained from the certificate) to construct a SKIP session as described previously. The actual message is encrypted and authenticated, a SKIP header 2205 is added, and an outer IP header 2203 is added, directing the message to server 407.

When the message reaches server 407, SKIP in server 407 checks the authentication on the message, decrypts it, and forwards the decrypted message to the HTTP service, which performs the access to the Web page requested by the message contained in the payload. Having obtained the Web page, the HTTP service makes a return message with an IP header specifying roamer 503 as the destination. This return message is then encapsulated in a SKIP message 2201 as previously described. This SKIP message is directed to access filter 403(5) and contains the information in outer header 2203 and SKIP header 2205 that is required for a message between those entities.

When the reply message reaches access filter 403(5), it is authenticated and decrypted by SKIP 2021 there, and forwarded to IP filter 2019. The message is found to match an existing session so evaluation is not needed; it is forwarded directly to HTTP proxy 2031. There it is checked for validity as an HTTP protocol reply message and retransmitted back to the originator of the HTTP session, which is access filter 403(3). Checking by the anti-virus module 2033 is not done since the originator of this session is known to be another access filter 403 in the VPN 201, as it is known that access filter will do the checking if needed. The retransmission of the reply is again processed through SKIP 2021 and encrypted as above, using the SKIP parameters required for an exchange between access filter 403(3) and access filter 403(5).

When this reply message reaches access filter 403(3), precisely the same thing occurs, that is, the message passes through SKIP 2021 and IP Filter 2019, to the http proxy 2031. There it is checked for validity as an HTTP protocol reply message, possibly passed through the anti-virus module 2033 (if the message content type warrants it), and

retransmitted back to the originator of the HTTP session, which is roamer 503. The transmission of the reply is again processed through SKIP 2021 and encrypted as above, using SKIP parameters as set forth above for a message being sent from access filter 403(3) to roamer 503. The reply message is then received at roamer 503, where it is authenticated and decrypted by SKIP, provided to the user's browser, and displayed for the user.

Conclusion

The foregoing *Detailed Description* has disclosed to those skilled in the arts to which the *Detailed Description* pertains the best mode presently known to the developers of the access filters disclosed herein of constructing and using access filters that overcome the scalability problems which prior-art prior-art access filters presented for virtual private networks. The scalability problems are overcome by a number of features of the access filter disclosed herein. Among them is an access control database which permits delegation of administrative authority and administration of a local copy of the access control database and thereby allows decentralization both with regard to administrative personnel and with regard to geographic location. The access control data base specifies access policies that determine which user groups may access which information sets, policy maker policies that determine which user groups may make access policies, and administrative policies which determine which user groups may administer objects in the virtual private network. It is these administrative policies which permit easy delegation.

Administrators can employ the graphical user interfaces disclosed herein to administer the access control data base. The clarity and ease of use of these graphical user interfaces makes it easy to delegate administrative authority to non-specialists. When an administrator makes a change in the access control data base, the change is first made in the local copy of the data base for a given access filter and then propagated to the local copies of the other access filters. The local copy of the access control database also makes it possible to efficiently implement a graphical user interface to the virtual private network which shows a user only those resources that belong information sets to which the user groups to which the user belongs have access.

Another feature of the access filter which contributes to scalability is the ability of the access filters in a virtual private network to authenticate sessions to each other. Because the access filters can do this, access checking of a request need only be done once, at the first access filter encountered by the request. The other access filters between the user and the information item need only determine whether the request has already been authenticated by another access filter, and if it has, pass the request through. Authentication of sessions by the access filters to each other thus both decreases the amount of access checking that need be performed and distributes the access checking that is done throughout the virtual private network.

Authentication also permits encryption to be done in the same fashion: the first access filter encountered by the request encrypts the request after it has checked the access, and the other access filters pass the encrypted request through without decrypting it until the last access filter before the server that contains the data item being accessed by the request is reached. Doing encryption and decryption in this fashion reduces the amount of encryption and decryption and distributes the encryption and decryption that is done in the same fashion as with access checking.

Another feature is that the access filter assigns a sensitivity level to an information set and a trust level to a mode of identification of a user making a request and permits the access only if the trust level is at least as great as the sensitivity level. In the preferred embodiment, identification by Internet address is assigned a low trust level and identification by cryptographic authentication with an X.509 certificate is assigned a high trust level. If the identification used by the user in making the request does not have a trust level sufficient for the sensitivity level, the access filter can interactively request that the user provide identification with a higher trust level.

The access filter also assigns trust levels to segments of the actual networks in virtual private network 201 and to encryption algorithms. The access filter analyzes the trust levels of the network segments between the user and the server that contains the information item, and any of them is lower than the information item's sensitivity, the

access filter requires that the session be encrypted with an encryption algorithm whose trust level is at least as high as the information item's sensitivity level. If a segment between the user and the first access filter or a segment between the last access filter and the server does not have the requisite trust level, the first access filter requires that the user or server encrypt the session with an encryption algorithm that has the requisite trust value before it will allow access; if a subsetment of the segment between the first access filter and the last access filter, the first access filter itself encrypts the session using an encryption algorithm that has the requisite trust level. By requiring only the trust level necessary for an information item's sensitivity, the access filter reduces the burden of access checking to what is actually required for the information item; by permitting the user to offer a more trustworthy identification and using encryption to upgrade the trustworthiness of a segment of the network, the access filter provides flexibility without compromising security. It should be noted that in other embodiments, the first access filter may encrypt the session as required for the server, providing of course that the encryption for the server is sufficient for the trust level of the resource.

While the *Detailed Description* has disclosed the best mode presently known to the developers of implementing the above features, it will be immediately apparent to those skilled in the arts relating to access filters that any number of other implementations which embody the principles embodied in the access filter disclosed herein are possible. For example, as pointed out in the *Detailed Description*, an access filter with the above features may be implemented as an application running under an operating system, as a component of an operating system, and/or as a component of a router. Since an unlimited number of other embodiments of the principles disclosed herein are possible, the *Detailed Description* is to be regarded as being in all respects exemplary and not restrictive and the breadth of the invention disclosed herein is to be determined not from the *Detailed Description*, but rather from the claims as interpreted with the full breadth permitted by the patent laws.

What is claimed is:

1. An access filter that administers objects including a plurality of information resources and controls access by a user to an information resource of the plurality, the access filter comprising:

access control information including

access policy information including one or more explicit access policies that determine which information resources a given user may request access to and

administrative policy information including one or more explicit administrative policies that determine at least whether a user may administer an object;

an access policy checker which responds to a request by a user to access a resource by denying the request if the access policy does not permit the access; and

an administrative policy checker which responds to a request by a user to administer the object by denying the request if the administrative policy does not permit the request.

2. The access filter set forth in claim 1 wherein:

the access policy information further includes user identification information; and

the access policy checker employs the user identification information to authenticate the user before determining whether the access policy permits the access.

3. The access filter set forth in claim 1 wherein:

the user employs a client to request access to the information resource;

the client includes a browser which displays a list of information resources accessible to the user according to the access policy; and

the access policy checker uses the access policy to determine which information resources are on the list for the browser.

4. The access filter set forth in claim 1 wherein:

the request may be a request to modify the object.

5. The access filter set forth in claim 1 wherein:

the request may be a request to modify a relationship between the object and another object.

6. The access filter set forth in claim 1 wherein:

the request may be a request to modify the administrative policy for the object.

7. The access filter set forth in any of claims 1 through 6 wherein:

the object is an access policy.

8. The access filter set forth in any of claims 1 through 6 wherein:

the access control information defines user subsets of the users and information subsets of the information resources; and

an access policy determines which information resource a user may access by defining which user subsets may access which information subsets.

9. The access filter set forth in claim 8 wherein:

the object is a user subset.

10. The access filter set forth in claim 8 wherein:

an administrative policy determines which object a user may administer by defining which user subsets may administer the object.

11. The access filter set forth in claim 8 wherein:

the object is an information subset.

12. The access filter set forth in claim 11 wherein:

an information resource has a sensitivity level associated therewith in the access policy information, the request to access an information resource has a trust level associated therewith, and

the information access checker permits access only if the trust level associated with the request to access the information resource is at least as high as the sensitivity level of

the information resource; and

the request may be a request to assign a sensitivity level to an information resource belonging to the information subset.

13. The access filter set forth in claim 12 wherein:

a user has a mode of identification associated therewith in the access policy information;

the trust level of the request to access the information resource is determined at least in part by a trust level of the mode of identification; and

the request may be a request to assign a trust level to a mode of identification.

14. The access filter set forth in claim 12 wherein:

the trust level of the request to access the information resource is determined at least in part by a trust level of a portion of a path in a network between the user and a server in the network which provides the information resource; and

the request may be a request to assign a trust level to the portion.

15. The access filter set forth in claim 12 wherein:

the trust level of the request to access the information resource is determined at least in part by a trust level of an encryption method used to encrypt the request; and

the request may be a request to assign a trust level to an encryption method.

16. The access filter set forth in any one of claims 1 through 6 wherein:

the objects are available resources in the virtual network.

17. The access filter set forth in any one of claims 1 through 6 wherein:

the objects are organized hierarchically; and

an access policy for a given object applies to objects that are below the given object in the hierarchy to which the object belongs.

18. The access filter set forth in any one of claims 1 through 6 wherein

the access filter is one of a plurality thereof in a network;

each access filter of the plurality has a local copy of the access control information; and

the access policy checker in each access filter employs the local copy to check access.

19. The access filter set forth in claim 18 wherein:

each access filter further comprises:

a policy editor which a member of an administrative user subset may use to make a modification of the local copy in accordance with the policy maker policy and/or the administrative policy; and

a distributor for providing the modification to the other access filters of the plurality.

20. The access filter set forth in claim 19 wherein:

another of the access filters maintains a master copy of the access control information; and

the distributor provides the modification to the other access filter, receives a master copy with the modification from the other access filter, and makes the master copy the local copy.

21. A data storage device for use in a system including a processor, the data storage device being characterized in that:

the data storage device contains code which, when executed in the processor, implements the access filter set forth in any one of claims 1 through 6.

22. The access filter set forth in any one of claims 1 through 6 wherein:

the access filter is implemented as an application program executing under an operating system.

23. The access filter set forth in any one of claims 1 through 6 wherein:

the access filter is implemented as a component of an operating system.

24. The access filter set forth in any one of claims 1 through 6 wherein:

the access filter is implemented as a component of a router in the network.

25. An access control system that controls access by users to information resources, the access control system comprising:

access control information including an access policy that is defined using explicit definitions of user subsets of the users, explicit definitions of information subsets of the information resources, and explicit access policy definitions indicating which user subsets may access which information subsets; and

an access policy checker which responds to a request by a user for access to an information resource by determining from the access policy the user subsets of which the user is a member, the information subsets of which the information resource is a member, and whether the explicit definitions permit access to an information subset of which the information resource is a member by a user subset to which the user belongs.

26. The access control system set forth in claim 25 wherein

the user subsets and the information subsets are organized hierarchically; and

an administrative policy for a given user subset and a given information subset applies to user subsets that are below the given user subset in the given user subset's hierarchy and to information subsets that are below the given information subset in the given information subset's hierarchy.

27. The access control system set forth in claim 25 wherein

the access control system further controls administrative access to objects and the access control system further comprises:

administrative policy that is defined using the definitions of user subsets, explicit definitions of objects administered by the access control system, and explicit administrative policy definitions of which user subsets may administer which objects; and

an administrative policy checker which responds to a request by a user to administer

an object by determining from the administrative policy whether the explicit administrative policy definitions permit a user subset to which the user belongs to administer the object.

28. The access control system set forth in claim 27 wherein:
the request may be a request to modify the object.

29. The access control system set forth in claim 27 wherein:
the request may be a request to modify a relationship between the object and another object.

30. The access control system set forth in claim 27 wherein:
the request may be a request to modify the administrative policy for the object.

31. The access control system set forth in any of claims 27 through 30 wherein:
the object is a user subset.

32. The access control system set forth in any of claims 27 through 30 wherein:
the object is an information subset.

33. The access control system set forth in any one of claims 27 through 30 wherein:
the objects are available resources in a network.

34. The access control system set forth in any one of claims 27 through 30 wherein:
the objects are organized hierarchically; and
an administrative policy for a given object applies to objects that are below the given object in the hierarchy to which the object belongs.

35. The access control system set forth in any one of claims 27 through 30 wherein;
the object is an access policy.

36. A data storage device for use in a system including a processor, the data storage

device being characterized in that:

the data storage device contains code which, when executed in the processor, implements the access control system set forth in any one of claims 25 through 30.

37. The access control system set forth in any one of claims 25 through 30 wherein:

the access control system is implemented as an application program executing under an operating system.

38. The access control system set forth in any one of claims 25 through 30 wherein:

the access control system is implemented as a component of an operating system.

39. The access control system set forth in any one of claims 25 through 30 wherein:

the access control system is implemented as a component of a router in the network.

40. The access control system set forth in claim 25 wherein the access policy checker further comprises:

an information subset information provider for a browser employed by the user to view a list of information subsets accessible to the user, the information subset information provider using the access policy to provide information about which of the information subsets are accessible to the user to the browser.

41. An administrative access control system that controls administration of objects by administrative users,

the system comprising:

administrative policy that is defined using explicit definitions of administrative user subsets of the administrative users, explicit definitions of objects administered by the administrative access control system, and explicit administrative policy definitions of which user subsets may administer which objects; and

an administrative policy checker which responds to a request by a user to administer an object by determining from the administrative policy whether the explicit administrative

policy definitions permit an administrative user subset to which the user belongs to administer the object.

42. The access control system set forth in claim 41 wherein:

the request may b a request to make administrative policy for the object, whereby a member of the administrative user subset may delegate authority to administer a given object to another user subset.

43. The access control system set forth in claim 41 wherein:

the request may be a request to modify the object.

44. The access control system set forth in claim 41 wherein:

the request may be a request to modify a relationship between the object and another object.

45. The access control system set forth in any of claims 41 through 44 wherein:

the object is a user subset.

46. The access control system set forth in any of claims 41 through 44 wherein:

the object is an information subset.

47. The access control system set forth in any one of claims 41 through 44 wherein:

the objects are available resources in a network.

48. The access control system set forth in any one of claims 41 through 44 wherein:

the objects are organized hierarchically; and

an administrative policy for a given object applies to objects that are below the given object in the hierarchy to which the object belongs.

49. A data storage device for use in a system including a processor, the data storage device being characterized in that:

the data storage device contains code which, when executed in the processor, implements the access control system set forth in any one of claims 41 through 42.

50. The access control system set forth in any one of claims 41 through 43 wherein:

the access control system is implemented as an application program executing under an operating system.

51. The access control system set forth in any one of claims 41 through 43 wherein:

the access control system is implemented as a component of an operating system.

52. The access control system set forth in any one of claims 41 through 43 wherein:

the access control system is implemented as a component of a router in the network.

53. A graphical user interface for an access control system that controls access by users to information resources according to an access policy that is defined using explicit definitions of user subsets of the users, explicit definitions of information subsets of the information resources, and explicit access policy definitions indicating which user subsets may access which information subsets,

the graphical user interface comprising:

a display upon which is displayed a list of user subsets, a list of objects, and a list of access policies, and at least an indication of a create access policy operation; and

a selection device for selecting a user subset from the list thereof, an information subset from the list thereof, and the indication of the create access policy operation,

the access control system responding to the selection of the user subset, the information subset, and the indication of the new access policy operation by establishing a new access policy for the selected user subset and the selected information subset.

54. The graphical user interface set forth in claim 53 further comprising:

an indication of a delete access policy operation; and

the selection device further selects an access policy from the list thereof and the

indication of the delete access policy operation;

the access control system responding to the selection of the access policy and the indication of the delete access policy operation by deleting the selected access policy from the list thereof.

55. The graphical user interface set forth in claim 53 wherein each access policy specifies one of a plurality of access types and

the user interface further comprises:

indications in the access policies on the list of their access types and

an indication of a change access type operation; and

the selection device further selects an access policy on the list thereof and the indication of the change access type operation,

the access control system responding to the selection of the access policy and the selection of the indication of the change access type operation by changing the access type of the selected access policy as specified by the indication of the change access type operation.

56. The graphical user interface set forth in any one of claims 53 through 55 wherein:

a user subset may itself have user subsets and an information subset may itself have information subsets; and

the list of user subsets shows the subset relationships among user subsets and the list of information subsets shows the subset relationships among the information subsets.

57. The graphical user interface set forth in any one of claims 53 through 55, the graphical user interface further comprising:

an indication of an evaluate operation,

the access control system responding to a selection of a user subset and a selection of the indication of the evaluate operation by the selection device by indicating the information subsets in the list thereof that the selected user subset may and/or may not access.

58. The graphical user interface set forth in claim 57 wherein:

the access control system further responds to the selection of the user subset and the selection of the indication of the evaluate operation by the selection device by indicating the policies in the list thereof that apply to the selected user subset.

59. The graphical user interface set forth in any one of claims 53 through 55, the graphical user interface further comprising:

an indication of an evaluate operation,

the access control system responding to a selection of an information subset and a selection of the indication of the evaluate operation by the selection device by indicating the user subsets in the list thereof that may and/or may not access the selected information subset.

60. The graphical user interface set forth in claim 59 wherein:

the access control system further responds to the selection of the information subset and the selection of the indication of the evaluate operation by the selection device by indicating the policies in the list thereof that apply to the selected information subset.

61. The graphical user interface set forth in any one of claims 53 through 55, the graphical user interface further comprising:

an indication of an evaluate operation,

the access control system responding to a selection of an access policy from the list thereof and a selection of the indication of the evaluate operation by the selection device by indicating the user subsets and information subsets in the lists thereof to which the selected policy applies.

62. A data storage device for use in a system including a processor, the data storage device being characterized in that:

the data storage device contains code which, when executed in the processor, implements the graphical user interface set forth in any one of claims 53 through 55.

63. A graphical user interface for an administrative access control system that permits

a user who belongs to an administrative subset of users to administer objects according to an administrative policy that is defined using explicit definitions of the objects and the administrative user subsets,

the graphical user interface comprising:

a display upon which is displayed a list which indicates objects that may be administered by the user and an indication of an administration operation; and

a selection device for selecting an object subset from the list thereof and the indication of the administration operation,

the administrative access control system responding to the selection of the object and the indication of the administer object operation by performing the administration operation with regard to the object.

64. The graphical user interface set forth in claim 63 wherein:

the display further displays a list of objects and

the administration operation is an add object operation;

the selection device further selects an object from the list thereof,

the administrative access control system responding to the selection of the object and the add object operation by adding the object.

65. The graphical user interface of either claim 63 or 64 wherein:

the objects are in the alternative user subsets, information subsets of information resources, and available resources.

66. The graphical user interface of either claim 63 or 64 wherein:

the appearance of an object on the list indicates whether the user may administer the object.

67. A data storage device for use in a system including a processor, the data storage device being characterized in that:

the data storage device contains code which, when executed in the processor, implements the graphical user interface set forth in either claim 63 or claim 64.

68. A user interface for a system in which access by users of the system to information resources in the system is mediated by an access control system which includes access control information that indicates access rights of users to resources,
the user interface comprising:

an access control information reader for responding to an identification of a user of the system by reading the access control information to determine at least those resources to which the user potentially has access and providing at least a list of those resources; and

an interface display generator for responding to the list by generating a display which visually indicates those resources to which the user potentially has access.

69. The user interface set forth in claim 68 wherein:
the user may access a given resource by one of a plurality of methods;
the list indicates a method of the plurality for each resource; and
the display further visually indicates for each resource the method of the plurality.

70. The user interface set forth in claim 69 wherein:
the plurality of methods includes access by activating a hyperlink when the user selects the resource in the display; and
when a resource may be accessed by means of a hyperlink, the list contains the hyperlink.

71. The user interface set forth in claim 69 wherein:
the plurality of methods includes access by activating a representation of a program for accessing the method, the representation being external to the display for the user interface.

72. The user interface set forth in claim 69 wherein:
the list of resources further contains resources to which the user does not presently have access but to which the user may request access;
when the user may request access, the list includes an email address for a user who is able to provide access; and

the display provides an email interface that the user can use to send email to the user who is able to provide access.

73. The user interface set forth in claim 68 wherein:

the access control information includes an indication for each resource whether the resource is to appear in the display when the user does not presently have access to the resource; and

if the indication indicates that the resource is not to appear, the access control information reader does not include the resource in the list.

74. The user interface set forth in claim 68 or 73 wherein:

the display further includes a filter specifier for specifying a manner in which the resources are to be filtered; and

the interface display generator filters the list as specified by the filter specifier and displays a result of the filtering.

75. The user interface set forth in claim 74 wherein:

the filter specifier specifies a resource to be searched for.

76. The user interface set forth in claim 68 wherein:

the access control information further defines access rights of the users to the resources in terms of access rights of sets of users to sets of resources.

77. The user interface set forth in any of claims 68 through 73 or claim 75 wherein:

there is a plurality of copies of the access control information in the system;

one of the plurality of copies is local to the interface display generator; and

the access control information reader in the local copy provides the list of resources to the interface display generator.

78. Apparatus for generating a display indicating resources in a system that can be accessed by a user of the system the resources being obtained for the user by a client in the

system from a server in the system and access by the user to the resources being mediated by an access control system that includes access control information that indicates access rights by users to resources, the apparatus being located in the client and the apparatus comprising:

a list produced by the access control system that indicates those resources that can potentially be accessed by the the user and

an interface display generator that receives the list and responds thereto by generating a display which visually indicates those resources to which the user potentially has access.

79. The apparatus set forth in claim 78 wherein:

the user may access a given resource by one of a plurality of methods;

the list indicates the method; and

the display further visually indicates for each resource the method of the plurality by which the user may access the resource.

80. The apparatus set forth in claim 79 wherein:

the plurality of methods includes access by activating a hyperlink when the user selects the resource in the display; and

when a resource may be accessed by means of a hyperlink, the list contains the hyperlink.

81. The apparatus set forth in claim 79 wherein:

the plurality of methods includes access by activating a representation of a program for accessing the method, the representation being external to the display for the apparatus.

82. The apparatus set forth in claim 79 wherein:

the list of resources further contains resources to which the user does not presently have access but to which the user may request access; and

when the user may request access, the list includes an email address for a user who may provide access; and

the display provides an email interface that the user of the client can use to send email to the user who may provide access.

83. The user interface set forth in claim 78 wherein:

the access control information includes an indication for each resource whether the resource is to appear in the display when the user does not presently have access to the resource; and

if the indication indicates that the resource is not to appear, the list does not include the resource in the list.

84. The user interface set forth in claim 78 or 83 wherein:

the display further includes a filter specifier for specifying a manner in which the resources are to be filtered; and

the interface display generator filters the list as specified by the filter specifier and displays a result of the filtering.

85. The user interface set forth in claim 84 wherein:

the filter specifier specifies a resource to be searched for.

86. Theapparatus set forth in claim 78 wherein:

the access control information includes an indication for each resource whether the resource is to appear in the display when the user does not presently have access to the resource; and

a resource which is not to be displayed is not included in the list.

87. The apparatus set forth in claim 86 wherein:

the display further includes a search specifier for specifying an item to be searched for; and

the interface display generator performs the search as specified by the search specifier on the list.

88. The apparatus set forth in claim 87 wherein:

the list of resources further contains resources to which the set of users does not presently have access but to which the user may request access; and

the access control system mediates the search such that the search is also made on resources to which the user may request access.

89. The apparatus set forth in claim 78 wherein:

the system includes one or more access filters, each access filter containing a copy of the access control information and the access filters including a local access filter local to the client and a server that provides a list display resource which is a downloadable program that implements the interface display generator;

the client makes a request for the list display resource, the access filter containing the list display resource responding thereto by downloading the downloadable program to the client; and

the downloadable program makes a request for the list, the local access filter responding thereto by using the local access filter's copy of the access control information to make the list and providing the list to the downloadable program.

90. Data storage apparatus which is readable by a processor, the data storage apparatus being characterized in that:

the data storage apparatus contains code which, when executed by the processor, implements the interface display generator of claim 78.

91. Apparatus that provides an information resource in response to a request from a user, the request including an identification of the user according to a mode of identification and the apparatus comprising:

access control information including

a sensitivity level associated with the resource and

a trust level associated with the mode of identification; and

an access checker which permits the apparatus to provide the resource only if the trust level for the mode of identification is sufficient for the sensitivity level of the resource.

92. The apparatus set forth in claim 91 wherein:

a plurality of the modes of identification are associated with the user, the plurality including at least authentication by means of a certificate for the user.

93. The apparatus set forth in claim 92 wherein:

the plurality of modes of identification further include at least authentication by token, authentication by IP address and/or domain name, and authentication by an operating system-provided ID.

94. The apparatus set forth in claim 91 wherein:

a plurality of modes of identification are associated with the user;

the identification of the user identifies the user according to one or more of the modes of identification; and

if the trust level associated with none of the identification's modes of identification presently known to the apparatus is sufficient for the sensitivity level, the apparatus requests further identification from the user.

95. The apparatus set forth in any one of claims 91 through 94 wherein:

the request is transferred via a path in a network;

the access control information further includes a path trust level associated with the path, the access checker further determining whether to permit the apparatus to provide the resource on the basis of the path trust level.

96. The apparatus set forth in any one of claims 91 through 94 wherein:

the access control information further includes an encryption trust level associated with an encryption method, the access checker further determining whether to permit the apparatus to provide the resource on the basis of the encryption trust level of the encryption method used to encrypt the access request.

97. The apparatus set forth in claim 96 wherein:

the access checker permits the apparatus to provide the resource only if the access

request has been encrypted with an encryption method whose encryption trust level is sufficient for the sensitivity level.

98. The apparatus set forth in any one of claims 91 through 94 wherein:

the access request is transferred via a path in a network; and

the access control information further includes

a path trust level associated with the path and

an encryption trust level associated with an encryption method,

the access checker further permitting the apparatus to provide the resource only if either the path trust level is sufficient for the sensitivity level or the access request has been encrypted with an encryption method whose encryption trust level is sufficient for the sensitivity level.

99. The apparatus set forth in claim 98 wherein:

the path is made up of one or more links;

the access control information further includes

a link trust level associated with each link; and

the path trust level is the link trust level of the link with the least sufficient trust level.

100. The apparatus set forth in claim 98 wherein:

a request made via the path is encrypted according to an encryption method; and

the path trust level is the encryption trust level of the encryption method.

101. The apparatus set forth in claim 91 wherein:

the resource is a World Wide Web page.

102. A data storage device for use in a system including a processor, the data storage device being characterized in that:

the data storage device contains code which, when executed in the processor, implements the apparatus set forth in claim 91.

103. The apparatus set forth in claim 91 wherein:

the apparatus is implemented at least in part as an application program executing under an operating system.

104. The apparatus set forth in claim 91 wherein:

the apparatus is implemented at least in part as a component of an operating system.

105. The apparatus set forth in claim 91 wherein:

the apparatus is implemented at least in part as a component of a router in a network.

106. Apparatus that provides an information resource via a path through a network to a user in response to a request from the user, the apparatus comprising:

access control information including

a sensitivity level associated with the resource,

a path trust level associated with the path, and

an encryption trust level associated with an encryption method; and

an access checker which permits the apparatus to provide the resource only if either the path trust level is sufficient for the sensitivity level or the encryption trust level is sufficient for the sensitivity level and the request is encrypted with the encryption method.

107. The apparatus set forth in claim 106 wherein:

the path is made up of one or more links;

the access control information further includes

a link trust level associated with each link; and

the path trust level is the link trust level of the link with the least sufficient link trust level.

108. The apparatus set forth in claim 106 wherein:

a request made via the path is encrypted according to an encryption method; and

the path trust level is the encryption trust level of the encryption method.

109. The apparatus set forth in claim 106 wherein:

the apparatus is located in the path between the user and the information resource; and

when the portion of the path that is located between the apparatus and the resource has a path trust level that is not sufficient, the apparatus encrypts the request using an encryption method whose encryption trust level is sufficient for the sensitivity level.

110. The apparatus set forth in claim 109 wherein:

when a portion of the path with a path trust level that is not sufficient is located between the apparatus and the user, the access checker permits the access only if the user has encrypted the request using an encryption method whose encryption trust level is sufficient for the sensitivity level.

111. The apparatus set forth in claim 106 wherein:

the apparatus is located in the path between the user and the information resource; and

when a portion of the path with a path trust level that is not sufficient is located between the one apparatus and the user, the access checker permits the access only if the user has encrypted the request using an encryption method whose encryption trust level is sufficient for the sensitivity level.

112. The apparatus set forth in any one of claims 106 through 111 wherein:

the path trust level is subject to change; and

the access checker checks the path trust level for every request.

113. A data storage device for use in a system including a processor, the data storage device being characterized in that:

the data storage device contains code which, when executed in the processor, implements the apparatus set forth in claim 106.

114. The apparatus set forth in claim 106 wherein:

the apparatus is implemented at least in part as an application program executing under an operating system.

115. The apparatus set forth in claim 106 wherein:

the apparatus is implemented at least in part as a component of an operating system.

116. The apparatus set forth in claim 106 wherein:

the apparatus is implemented at least in part as a component of a router in the network.

117. An improved access filter of the type which receives an access request via a network, the access request requesting access by a user to an information resource, the access control system making a determination whether the user may have access to the resource, and

the improved access filter having the improvement comprising:

an access check confirmer that determines whether another access control system in the network has already made the determination, the access check confirmer causing the access filter to make the determination only if the determination has not already been made by another access filter.

118. The access filter set forth in claim 117 wherein:

when the determination indicates that access will be allowed, authentication information indicating that the access check was made by the access filter is added to the access request.

119. The access filter set forth in claim 118 wherein:

the authentication information is an identifier for a public key belonging to the access filter that makes the access check and an encrypted digest of the access request that may be decrypted with the public key belonging to the access filter that makes the access check.

120. The access filter set forth in any of claims 117 through 119 wherein:

as part of handling the returned data from the access request, the access filter further checks the data for a virus and does not allow any virus laden data to be returned to the requestor.

121. An improved access filter which is used together with a plurality of other access filters in a network that further includes clients and servers that provide information resources to the clients via a path in the network in response to an access request from a user on a client, the access filters each being capable of making a determination whether the access request should be allowed, and if the request is to be allowed, encrypting the request, the access filter having the improvement comprising:

an access check confirmer that determines whether another access filter has already made the determination and when that is the case, passing the encrypted request along the path without decrypting the request.

122. The improved access filter set forth in claim 121 wherein:

the path to an information resource includes a last access filter through which the request passes en route to a server of the servers that provides the information resource;

when the access filter is the other access filter, the other access filter directs the encrypted request to the last access filter; and

when the access filter is the last access filter, the request is decrypted and routed to the server.

123. The access filter set forth in claim 122 wherein:

each of the access filters has a key for encrypting requests to be decrypted by the access filter;

each of the access filters has routing information from which the last access filter can be determined and key information which gives the access filter access to the key belonging to the last access filter; and

when the access filter is the other access filter, the request is encrypted using the key belonging to the last access filter.

124. The access filter set forth in claim 121 wherein:

when the access check confirmer determines that an access check has not been made, the access filter makes the determination and when the determination indicates that access will be allowed, the access request is encrypted.

125. The access filter set forth in claim 124 wherein:

the client encrypts the access request before sending the request to the access filter; and

when the access check confirmer determines that the access check has not been made, the access request is decrypted prior to making the determination.

126. The access filter set forth in claim 124 wherein:

when the determination indicates that access will be allowed, authentication information indicating that the access check was made by the access filter is added to the encrypted access request.

127. The access filter set forth in claim 126 wherein:

the authentication information is an identifier for a public key belonging to the access filter that makes the access check and an encrypted digest of the access request that may be decrypted with the public key belonging to the access filter that makes the access check.

128. The access filter set forth in claim 124 wherein:

a plurality of encryption methods are employed in encrypting the request;

each of the access filters specifies a sensitivity level for the resource and a trust level for each of the encryption methods; and

the access filter uses the trust level and the sensitivity level to determine the encryption method.

129. The access filter set forth in any one of claims 124 through 127 wherein:

each of the access filters has a key for encrypting requests to be decrypted by the

access filter;

each of the access filters has routing information from which the last access filter can be determined and key information which gives the access filter access to the key belonging to the last access filter; and

the key belonging to the last access filter is used in encrypting the access request.

130. The access filter set forth in any one of claims 124 through 127 wherein:

the server that provides the resource has a key for encrypting requests to be decrypted by the server;

the access filter nearest the server has key information which gives the access filter access to the public key belonging to the server; and

the access filter nearest the server reencrypts the access request using the key belonging to the server.

131. An access filter which is used as one of a plurality of access filters in a network, the access filter serving to make a determination whether a request for access by a user to an information resource will be permitted and the network further including a client from which the user makes the request via a path in the network that includes at least one of the acess filters and a server that provides the information resource in response to the request, the access filter comprising:

a local copy of access control information that indicates whether the user may access the resource;

an access checker which employs the local copy to make the determination; and

an access check confirmer that determines whether another access filter in the path has already made the determination and only causes the access checker to make the determination if no other access filter has done so.

132. The access filter set forth in claim 131 further comprising:

an encrypter/decrypter for encrypting and decrypting the request; and

when the determination is that the request will be permitted, the encrypter/decrypter encrypts the request.

133. The access filter set forth in claim 132 wherein:

the encrypter encrypts the request such that the request can be decrypted by the encrypter/decrypter in the last access filter in the path.

134. The access filter set forth in claim 133 wherein:

the encrypter can encrypt the request according to a plurality of encryption methods;

the access control information associates a sensitivity level with the resource and a trust level with each of the plurality of encryption methods; and

the encrypter encrypts the request using an encryption method of the plurality such that the trust level of the encryption method is at least equal to the sensitivity level of the resource.

135. The access filter set forth in claim 132 wherein:

the client encrypts the request; and

the access filter employes the encrypter-decrypter to decrypt the request prior to making the determination.

136. The access filter set forth in any one of claims 131 through 135 further comprising:

an authenticator for making an authentication for the request;

when the determination is that the request will be permitted, the access filter employs the authenticator to produce authentication information that authenticates the request and adds the authentication information to the request; and

the access check confirmer determines from the added authentication information whether another access filter has already made the determination.

137. The access filter set forth in claim 131 further comprising:

an editor for making a change in the local copy of the access control information; and

a change propagator for propagating the change to others of the plurality of access filters.

138. The access filter set forth in claim 137 wherein:

the access control information further indicates whether a given user may make a change in a predetermined part of the local copy; and

the access checker further employs the local copy when a user employs the editor to make a particular change to make a determination whether the user is permitted to make the particular change.

139. The access filter set forth in claim 138 wherein:

the access control information further permits a given user who may make a change in the predetermined part to delegate making the change to another user.

140. A data storage device for use in a system including a processor, the data storage device being characterized in that:

the data storage device contains code which, when executed in the processor, implements the access filter set forth in any one of claims 117, 121, or 131.

141. The access filter set forth in any one of claims 117, 121, or 131 wherein:

the access filter is implemented as an application program executing under an operating system.

142. The access filter set forth in any one of claims 117, 121, or 131 wherein:

the access filter is implemented as a component of an operating system.

143. The access filter set forth in any one of claims 117, 121, or 131 wherein:

the access filter is implemented as a component of a router in the network.

MMF File Name	Contents
	Policies, User Groups, and Information Sets 2305
DBUsersFile 2307	Describes policy application from the User Group viewpoint. Maps each DB UserGroupID to a list of ResourceGroupIDs with flags that indicate whether the policy that relates each pair is an allow or deny policy.
DBUsersTreeFile	Describes the user groups tree as a flattened array. Maps each DB UserGroup ID to a list of UserGroupIDs for parent user groups
DBResourcesFile 2309	Describes policy application from the Resource Group (information set) viewpoint. Maps each DB ResourceGroupID to a list of UserGroupIDs with flags that indicate whether the policy that relates each pair is an allow or deny policy.
DBResourcesTreeFile	Describes the resource groups tree as a flattened array. Maps each DB ResourceGroupID to a list of ResourceGroupIDs for parent information sets.
	User Identification Information 2311
DBIPRangesFile	IP Ranges data. Maps from IPRangeDefID to the IP range data.
DBDomainsFile	IP Domain data. Maps from DomainDefID to the IP domain data.
DBCertificatesFile	Certificate data. Maps from CertificateDefID to the certificate data.
DBWindowsIDFile	Windows ID data. Maps from WindowDefID to the windows ID data.
DBSmartCardIDFile	Smart card (authentication token) data. Maps from Smartcard-DefID to the authentication token data.
DBIPRangesByUserGroup File	Relates IP range matching criteria to user groups. Maps from IP Range data to UserGroupIDs.
DBDomainsByUserGroup File	Relates IP domain matching criteria to user groups. Maps from IP Domain data to UserGroupIDs.
DBCertificatesByUserGroup File	Relates certificates to user groups. Maps from certificate data to UserGroupIDs. 2101
DBWindowsIDByUserGroup File	Relates Windows IDs to user groups. Maps from Windows ID data to UserGroupIDs.
DBSmartCardIDByUser GroupFile	Relates Smart Card (authentication token) data to user groups. Maps from authentication token data to UserGroupIDs

FIG. 23B

MMF File Name	Contents
	Servers, Services, and Information Resources 2313
DBResourcesByServerIDFile	Relates servers to resources. Maps from ServerIDs to ResourceIDs for resources held on the server identified by the ServerID.
DBResourcesByServiceIDFile	Relates services to resources. Maps from ServiceIDs to ResourceIDs for resources belonging to the service identified by the ServiceID.
DBResourceIDByServiceIDFile	Relates services to their information resources. Maps from ServiceID to ResourceID.
DBResourceIDByNameFile 2315	Relates the IP names (URLs) of resources to resource IDs. Maps from URL to resource ID.
DBResourcesByResourceIDFile 2317	Relates resources to information sets. Maps ResourceID to Resource GroupIds.
	Servers, Services, IP Information, and Proxies 2319
DBServerIDByIPFile	Relates IP addresses to servers. Maps IP addresses to ServerIDs.
DBServerIDByNameFile	Relates IP names to servers. Maps the IP FQDN (fully qualified domain name) for each server to its ServerID.
DBIPAndTypeByServerIDFile	Relates servers to their locations inside or outside to the VPN. Maps ServerID to the server's IP address and a flag indicating whether the address is inside or outside the VPN.
DBServiceIDByPortFile	Relates services to their port numbers. Maps from ServiceID to port number.
DBServiceIDByServerIDFile	Relates servers to ports for services. Maps from ServerID to a list of port numbers.
DBServicePortToProxyPortFile	Relates service ports to the ports for their proxies. Maps from service port number to proxy port number.
DBProxyIDByServerIDFile	Relates servers to service proxies. Maps from ServerID to ProxyDefID.
DBProxyParametersFile	Relates proxies to configuration data for the proxies. Maps from ProxyDefID to options data

2301

FIG. 23C

MMF File Name	Contents
	Access Filter Information 2321
DBAttachedNetworksByIPFile	Relates network interfaces in the access filters to information for the interfaces. Maps from the interface's IP address to interface information.
DBAttachedNetworksByServerIDFile	Relates access filters to their network interfaces. Maps from ServerID for the access filter to interface information.
DBRoutingTableFile	Describes the IP routing information for all of the access filters. One block of information.
DBRoutingTableByServerIDFile	Relates access filters to their IP routing information. Maps from ServerID for the access filter to IP routing information.
DBPointToPointFile	Relates a point-to-point description of a network path to data for the path. Maps from PointToPointID for the path to the associated data.
	SEND Information 2323
DBTrustTableFile 2325	Implements the SEND table. Maps from TrustDefID, indicating a trust level, to AuthenticationIDs for user identification techniques and EncryptionIDs for encryption techniques.
DBCertificateAuthoritiesFile	Relates identifiers for cerfiticate authorities to their data. Maps from CertificateAuthorityID to associated data.
DBTrustAuthenticationsFile	Relates AuthenticationIDs to information about identification techniques. Maps from AuthenticationID to identification technique information.
DBTrustEncryptionsFile	Relates EncryptionIDs to information about encryption techniques. Maps from EncryptionID to encryption type and strength information.
	IntraMap Information 2422
DBJavaSiteTable	Maps from names of locations to LocationIDs.
DBJavaResourceTable	Maps from URLs of resources to their ResourceIDs, LocationIDs, and *hidden* flags.
DBJavaResourcesSetTable	Maps from names of information sets to ResourceGroupIDs, a list of ResourceIDs for all resources contained in the information set, and a list of ResourceGroupsIDs for all of the information set's parents.

(54) Title: METHODS AND APPARATUS FOR CONTROLLING ACCESS TO INFORMATION

(57) Abstract

A scalable access filter that is used together with others like it in a virtual private network to control access by users at clients in the network to information resources provided by servers in the network. Each access filter uses a local copy of an access control data base to determine whether an access request is made by a user. Changes made by administrators in the local copies are propagated to all of the other local copies. Each user belongs to one or more user groups and each information resource belongs to one or more information sets. Access is permitted or denied according to access policies which define access in terms of the user groups and information sets. The rights of administrators are similarly determined by administrative policies. Access is further permitted only if the trust levels of a mode of identification of the user and of the path in the network by which the access is made are sufficient for the sensitivity level of the information resource. If necessary, the access filter automatically encrypts the request with an encryption method whose trust level is sufficient. The first access filter in the path performs the access check and encrypts and authenticates the request; the other access filters in the path do not repeat the access check.

PCT/US 98/04522

A. CLASSIFICATION OF SUBJECT MATTER
IPC 6 H04L29/06 H04L12/24 G06F1/00

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
IPC 6 H04L G06F

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	CHE-FN YU: "ACCESS CONTROL AND AUTHORIZATION PLAN FOR CUSTOMER CONTROL OF NETWORK SERVICES" COMMUNICATIONS TECHNOLOGY FOR THE 1990'S AND BEYOND, DALLAS, NOV. 27 - 30, 1989, vol. 2, 27 November 1989, INSTITUTE OF ELECTRICAL AND ELECTRONICS ENGINEERS, pages 862-869, XP000144900 see page 862, left-hand column, paragraph 1 - page 865, right-hand column, paragraph 4 --- -/--	1,25,41

[X] Further documents are listed in the continuation of box C.

[X] Patent family members are listed in annex.

* Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

Form PCT/ISA/210 (continuation of second sheet) (July 1992)

INTERNATIONAL SEARCH REPORT

Inter..ional application No.
PCT/US 98/04522

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.

2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

1-52

Remark on Protest

☐ The additional search fees were accompanied by the applicant's protest.

☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

1. Claims: 1-52

Access control system comprising access policy information, administrative policy information, an access policy checker and an administrative policy checker.

2. Claims: 53-90

Graphical user interface for displaying and selecting a user subset and an information subset and for displaying a list of resources that are available to a user.

3. Claims: 91-116

Apparatus associating a trust level to a user identification and a sensitivity level to a resource.

4. Claims: 117-143

Apparatus comprising a confirmer to avoid duplication of a checking process.
